> Vygotsky, 1978: p. 86

Contrary to Piaget, Vygotsky is of the view that learning leads cognitive development, and does not follow it. Through his sociocultural theory and particularly the concept of ZPD of Vygotsky, he in fact emphasized the role that the society can play in the process of cognitive development of an individual. Later research in this field provided further evidence regarding the role of culture in cognitive development (Arnett and Maynard, 2013; Rogoff, 2003; Sternberg, 2004).

Analyzing her research spread over a period of two to three decades, Rogoff (2003) concludes that cultural processes are of crucial importance in human development. She argues that cognitive development not only involves skills and knowledge at an individual level but also is a collective and collaborative endeavor, involving other people around an individual who are part of his or her immediate environment. She describes learning as a process of 'guided participation' shared by the child and other adults in the community. Similarly, Arnett and Maynard (2013) are of the view that human beings are biologically and culturally destined to language and other cultural tools and to learn from each other. They argue that the Western notion of cognitive development cannot be overgeneralized and applied to other cultures because each culture has different bearings on the cognitive developmental process depending upon its values, customs and traditions, and practices. Likewise, Sternberg (2004) emphasizes studying the cognitive development process in cultural context. He argues that if one tries to study intelligence acontextually, one will not be able to understand the phenomenon but will impose one's own view on the rest of the world.

It is basically the recognition of role of culture and adults in the intellectual development, particularly through mediation that provided the perspective and paved the way to explore the possibility of accelerating cognitive development of children and adolescents by way of human intervention (Adey and Shayer, 2014; Iqbal and Shayer, 2000; Shayer, 1999).

Educational Implications of Cognitive Development Theories

Although Piaget was interested in describing how the ability to think and making sense of the world develops in children, he did not talk explicitly about what schools should do in making the learning process more effective. He, however, has described some general principles of learning and that how the environment should be shaped to facilitate cognitive development of children. For example, Piaget believes that learning is an internal process of construction. He argues that learning cannot be deduced from observation or experience alone but is subordinated to developmental needs (Collins, 2002).

Therefore, for children to learn, they must be able to assimilate in order to respond to new concepts or experiences. Piaget thinks that children learn not only by observation but also through a process of self-regulation – a process called equilibration. In this process, they not only record what is going on but also reorganize and coordinate their own activities to form rules and principles.

Vygotsky, on the other hand, argues that learning is a collaborative process where meanings are constructed through the process of social interaction, questioning, discussion, and dialog. Subsequent research in these two domains leads to the conclusion that these two theories are in fact compatible and complement each other. Further work by von Glasersfeld (1990, 1995), Gergen (1985), Salomon and Perkins (1998), and Richardson (1997) in this perspective gave rise to a new school of thought called constructivism. Piaget's and Vygotsky's theories (constructivism) have implications for education, including teaching, learning, curriculum, and assessment. Some of these are as follows:

- Promote inquiry learning
  Piaget emphasized that children learn best when they are active and seek solutions to their questions for themselves. Piaget is opposed to the teaching methods that treat children as passive recipient of information. Hence teachers should promote inquiry learning by providing students with opportunities of exploring the material, setting up experiments, making observations, and drawing conclusions. Teachers should not only respect students' ideas and accept their autonomy, but also encourage them to take initiatives.
- Facilitate learning, do not direct teaching
  Instead of direct teaching and passing information to students in transmission mode, teachers should act as facilitators, helping students to construct their own meanings. Teachers should ask open-ended questions and generate discussion in the class.
- Promote students' questioning and cooperative learning
  In addition to questioning and discussion initiated by the teacher, students should also be encouraged to put questions to the teacher and to one another, seek clarification, and offer explanations. Vygotsky believed that it is not just adults who are important in helping students learn important skills. Students also benefit from the support and guidance offered by more capable peers. Group work, tasks, and assignments should be given to afford students opportunities to work cooperatively.
- Consider child's prior knowledge and level of thinking
  Students come to class with many ideas about the physical and natural world. They have concepts of space, time, quantity, and causality. Although these ideas differ from the ideas of an adult, they are very important from a child's point of view. Teachers need to ascertain children's prior ideas, interpret them, and address those ideas in a manner that is within the cognitive reach of the children.
- Use scaffolding
  Teachers should look for opportunities to use scaffolding when students need help for completing tasks and assignment. They should refrain from providing them correct answers or solutions. They should provide just enough help to the students to arrive at conclusion by themselves.
- Teach in the zone of proximal development
  Vygotsky's concept of zone of proximal development has a good practical value. He believes that social interaction in the class takes the students to the next higher mental level. Teachers should not be able to determine students' current level of development but arrange activities that lead toward further development.
- Aim at students' intellectual growth
  For Piaget, children's learning should occur naturally. He did not endorse the idea of pushing children to achieve too much too early in their development, before they are mature enough to process the given information. When Piaget came to lecture in the United States, he was asked, "What can I do to get my child to a higher cognitive stage sooner?" He was asked this question so often that he called it the 'typical American question.' But as mentioned earlier, subsequent work involving Vygotsky's concept of social construction and mediation made it possible to achieve such objectives. Teachers need to provide a stimulating environment by setting challenging tasks, discrepant events, cognitive dissonance, discussion, and dialog that provoke thinking in students and hence promote intellectual growth.
- Use continuous assessment and assessment for learning
  Constructivists believe that students construct their own meanings to make sense of the world around them. One standardized method will not fit for all. Teachers need to use a variety of techniques, both oral and written, to ascertain students' learning and feed that information for improving learning.
- Assess the ZPD, not the intelligence quotient (IQ)
  Teachers should learn the methods, procedures, and competence to measure children's ZPD to be able to adopt appropriate pedagogical skills and to take them to the next higher level of thinking. Vygotsky argues that formal, standardized assessment tests or IQ tests cannot provide measures to ascertain ZPD.

Abstract

The first few years of life are a period of rapid brain and cognitive development. This article outlines the general structural and functional changes in the brain that underlie cognitive development during infancy, and uses examples from the domains of face processing, language development, memory, and numerical cognition to illustrate these developmental processes. The article also briefly introduces the imaging technologies and research methods that are currently used to study brain and behavioral development in infancy.

Introduction

From the first moments of life, infants are developing the neural and behavioral capacities that will form the foundation upon which their future development rests. Newborns only a few minutes to a few hours old, for example, preferentially attend to human speech sounds over nonspeech sounds (Ecklund-Flores and Turkewitz, 1996), and to faces or facelike stimuli over other visual aspects of their surroundings (Johnson et al., 1991). The capacity for rapid auditory processing develops early in infancy, and is believed to be an important precursor of speech perception and processing and later language development (Sheridan et al., 2010). Infancy is, thus, a critical period of rapid cognitive development, which is both produced by and capable of influencing the maturation of brain structures and functional neural circuits. The past decade has seen a vast expansion of our knowledge on the neural mechanisms of infant cognitive development, the major principles of which are discussed in detail in the following sections.

Structural Brain Development in Infancy

A discussion of the neural basis of cognitive development necessarily begins with development of the brain structures and overall architecture that are the substrates of cognition and behavior. Structural brain development begins shortly after conception, and – depending on how it is defined – continues late into adolescence or adult life. Our most detailed understandings of how structural brain development contributes to cognition come from studies using animal models, postmortem brain tissue analyses, and, more rarely, those cases in which fetal or infant brain development is disrupted, leading to atypical cognitive outcomes. As such, it is important to note that our knowledge in this area may not reflect the most normative human developmental trajectories. However, newer neuroimaging technologies – some of which are introduced in the following sections – are already being used to study the links between brain and cognitive development more directly in awake and active infants and young children, and thus to deepen our understanding of the structural substrates of cognition in typical human development.

The precursor of the entire central and autonomic nervous system is the neural plate, which arises from the outermost layer of embryonic tissue, formed from multiplication of the single-celled zygote. Around the 4th week of gestation, this neural plate folds inward and forms the neural tube, which then differentiates into spinal cord and brain tissue, including the structures that will become the developed forebrain, midbrain, and hindbrain. Differentiation of the neural tube into the distinct structures of the nervous system is called *neurulation*, and is induced by chemical growth factors. Evidence of the importance of neurulation for future brain and cognitive development comes from studies of disorders of this process such as holoprosencephaly, in which the forebrain fails to develop cleanly into right and left hemispheres. In rare cases, in which children born with holoprosencephaly survive beyond infancy, these children show profound cognitive (and physical) delays starting in infancy; they usually develop little to no expressive language or higher level cognitive functions, although they have been observed to develop some receptive language at a delayed pace (Barr and Cohen, 1999).

Beginning around the 5th gestational week, neural progenitor cells proliferate rapidly, then develop axons and dendrites, a process known as neurogenesis. The proliferation of progenitor cells peaks by the 3rd or 4th month of gestation, and the development of axons and dendrites continues well into the 2nd year of postnatal life. New neurons formed prenatally migrate from the inside out, eventually giving rise to the six-layered cortex – the seat of cognition (Nelson et al., 2006). In humans, prenatal neurogenesis and neuronal migration are responsible for the majority of neurons comprising the brain throughout the lifetime, although neural progenitor cells present in the subventricular and hippocampal subgranular zones contribute to neurogenesis in the olfactory bulb and hippocampus into adulthood (Bonfanti and Peretto, 2011), and the prefrontal cortex up to 18 months of age (Sanai et al., 2011).

Disorders of neurogenesis in humans tend to result either in macroencephaly (large brain) or microencephaly (small brain; Nelson et al., 2006). Both these disorders and those implicated as disorders of abnormal dendritic growth (such as Rett syndrome and tuberous sclerosis) are frequently associated with mental retardation, although they usually cooccur with significant modifications in neuronal differentiation and

connectivity, making it difficult to tease apart the distinct effects of cortical neurogenesis on cognitive development. Our knowledge of the distinct effects of neurogenesis on cognition instead comes from animal studies such as those in which the antimitotic agent methylazoxymethanol (MAM) is delivered to rats during discrete periods of gestation. The offspring of rats treated with MAM at the period of gestation during which neurogenesis is at its peak experience a 50% reduction in cortical thickness, but exhibit surprisingly moderate alterations in cognitive abilities (Berger-Sweeney and Hohmann, 1997). In fact, the most consistently observed abnormality in these rats is hyperactivity, which may account for their altered performances in other cognitive tasks, such as deficits in spatial recognition, memory, and social interaction (Hazane et al., 2009). Thus the cerebral cortex might be sufficiently plastic to compensate for the loss of early neuron populations later in development.

Synaptogenesis – which typically begins in the 23rd week of human gestation – refers to the formation of points of contact between neurons. This process continues throughout postnatal life, resulting in an overproduction of synapses during or near the first year of life in most regions of the brain. Synaptic overproduction is then followed by a protracted period of synaptic pruning, which is highly experience-dependent; synapses are relatively unstable when they are first formed, and they are either reinforced and maintained by continued activation, or pruned away until adult numbers and densities of synapses are reached. Different brain structures follow different developmental courses in terms of synaptic overproduction and pruning, however. Synaptic densities in primary sensory areas such as the auditory cortex of the temporal lobe, for example, typically reach their peak at about 3 months of age, whereas the density of synapses in the middle frontal gyrus of the prefrontal cortex peaks after 15 months (Huttenlocher and Dabhoklar, 1997). Synapses in the visual cortex decrease to about half their maximum level when children are between 1 and 5 years of age, remaining stable after age 5, while synaptic density in the prefrontal cortex typically only begins to decrease around age 7 (Huttenlocher, 1999) and continues well into the third decade (Petanjek et al., 2011).

During and proceeding from synaptogenesis, spontaneous neuronal firing – independent of external stimuli and thus likely under genetic control – occurs throughout the brain. Additionally, sensory activity, chemical and cellular factors, and environmental stimuli may produce impulse transmission between neurons. Such neuronal firing, if temporally and/or spatially synchronized, forms neural circuits that become integrated and reinforced with continued activation. Brain function arises from the ongoing modulation, enhancement, synchronization, and integration of these neural circuits. Moreover, the plasticity that synaptic overproduction affords and the experience-dependent nature of synaptic pruning likely underlie the developmental course of individual cognitive abilities over the life span. In the domain of language acquisition, for example, as the auditory cortex matures over the first 3 months of life, infants are increasingly able to discriminate the sounds of most languages in the world, regardless of their own language environments: in the first hours and days of life, they show preferences for their native languages (Moon et al., 1993) and they can discriminate their native languages from those of relatively dissimilar language families (Mehler et al., 1988; Mehler and Christophe, 1994; Nazzi et al., 1998); by 4 or 5 months, when synaptic production in the auditory cortex has typically peaked, infants are able to discern their native languages from very close neighbors (Nazzi et al., 1998). In their hallmark studies, Werker and Tees (1983) demonstrated that infants then develop from being able to discriminate both native and nonnative phonemic contrasts to showing an adult-like inability to discriminate nonnative contrasts around 10–12 months of age – coinciding with the onset of synaptic pruning in sensory brain regions. A similar developmental course of cognitive maturation followed by 'perceptual narrowing' has also been observed in the domain of face processing (Nelson, 2001). The 'face-inversion effect' – in which inverted faces are harder to recognize than upright faces – is often used as a marker of expertise in face processing, as it indicates that upright faces belong to a special class of visual stimuli that are rapidly and automatically processed, although they are identical in perceptual properties to inverted faces. Infants develop the face-inversion effect around 4 months of age (Fagan, 1972) as synaptic connections in their visual system are growing and being reinforced, and the ability of infants to discriminate between different faces of nonhuman species declines between 6 and 9 months of age (Pascalis et al., 2002), when synaptic pruning occurs in the visual cortex.

Alongside synaptogenesis and pruning, myelination – the wrapping of an insulating fatty myelin sheath around axons – begins during the 5th month of fetal development. Myelination follows an organized and predictable temporal sequence, beginning at the brainstem and progressing from posterior to anterior regions, then from deep structures to superficial layers of the brain (Ballesteros et al., 1993). The myelination process continues through to the second decade of life, although its most dramatic changes occur during the first year of postnatal development: the base of the brain is myelinated around birth, and deep structures throughout the brain become myelinated by 6 months of age. The cerebral cortex – the last region to myelinate – begins to develop myelin first in the occipital lobe, and then in the frontal, parietal, and temporal lobes, respectively, between 8 and 12 months of age (Paus et al., 2001).

Myelination facilitates more efficient transmission of neural signals and thus establishes rapid communication pathways throughout the brain. It also allows for more synchronized activity within and between neural networks (Deoni et al., 2012). Increases in myelin are associated with domain-general cognitive developments such as the increased information encoding capabilities and processing speeds observed in infants over the first year of life (Richmond and Nelson, 2007; Webb et al., 2005). Additional evidence for the role of myelination in cognition comes from studies of developmental and psychiatric disorders such as autism, attention deficit hyperactivity disorder (ADHD), schizophrenia, and bipolar disorder, in which aberrant myelin development has been detected, and appears to contribute to the underconnectivity or desynchronized brain activity that may underlie cognitive dysfunction (Just et al., 2012; Meda et al., 2012; Mills et al., 2012).

Technologies such as structural magnetic resonance imaging (MRI) – which produce macrostructural images of the brain and can be used to measure white matter density and

cortical thickness associated with myelination – and diffusion tensor MRI – which is sensitive to the architecture of tracts and fibers throughout the brain – have made it possible to trace the development of myelin throughout even the deepest structures in the brains of infants and young children. Our current understanding of myelin progression in the typically developing infant brain is thus becoming more and more extensive; research in the near future may even be able to answer questions of individual differences in myelination, in order to provide a more precise and extensive picture of the role of myelin in cognitive development. For example, increasing sophistication in imaging resolution and analysis techniques may enable the quantification of variations in myelination between individuals, and investigations of the relationships between these differences and observable cognitive differences between infants and young children.

Functional Bases of Cognitive Development in Infancy

Studies such as those explored above, in which changes in brain morphology are linked to cognitive changes in humans, tend to be correlational in nature. In order to move beyond the level of association, it is necessary to observe the brain directly during specific cognitive tasks. The development of noninvasive imaging technologies – such as electroencephalography (EEG) and derived event-related potentials (ERPs), functional magnetic resonance imaging (fMRI), magnetoencephalography (MEG), functional near-infrared spectroscopy (fNIRS), or multimodal applications that may include combinations of the above – has enabled researchers to do just this.

EEG and ERPs use electrodes placed on the scalp to detect the electrical activity produced by neuronal firing within the brain. MEG provides a similar measure of brain activity, by recording the magnetic fields associated with these electrical currents. As such, MEG, EEG, and ERPs allow researchers to detect correlates of brain function that occur on the timescale of synaptic transmission, and studies utilizing these techniques thus have very high temporal resolution. fMRI, on the other hand, measures metabolic changes, specifically the blood-oxygen-level-dependent (BOLD) change, associated with increased neural circuit activation. The BOLD response occurs on a protracted timescale compared to neuronal activity, and while fMRI lacks the temporal resolution of EEG/ERP, it is useful for providing measures of brain activation with high spatial resolution. fMRI also has the advantage of providing detailed images of the brain without exposure to ionizing radiation, such as that used in positron emission tomography (PET). fNIRS is a newer imaging technology that, similar to fMRI, measures metabolic changes associated with brain activity in the cerebral cortex. While fNIRS lacks the spatial resolution for imaging deep structures that fMRI affords, it produces individual measures of oxyhemoglobin, deoxyhemoglobin, and total hemoglobin flow to the cortex, and due to its minimalistic hardware, noiseless data acquisition properties, and relative tolerance of participant movement, has distinct advantages for the functional neuroimaging of waking infants in active cognitive tasks. Although most of the research using these imaging technologies has so far been carried out on adult populations, these tools are increasingly being used to investigate the neural mechanisms underlying cognition in infants and children, and thus provide a developmental perspective on brain function over time (see **Figure 1**).

Developmental neuroimaging studies have elucidated several general principles of functional neural development, which underlie the cognitive development that is observable over the first few years of life. At a fundamental level, functional activity associated with cognition tends to progress from subcortical to cortical localization over infancy. Face processing, for example, is likely subserved by subcortical regions in newborns, who have been shown to preferentially attend to faces, facelike stimuli and direct eye contact from as early as the first hours of postnatal life (Farroni et al., 2002; Johnson et al., 1991); basic visual cortical function, however, is not thought to

Figure 1 Advances in noninvasive neuroimaging technologies are enabling researchers to elucidate the neural substrates of cognitive development in typically developing infants and young children. On the left, a 7-month-old is fitted with a high density electrode cap for the acquisition of EEG and ERP data. At right, minimalistic fNIRS hardware fits into a cap and enables the measurement of oxyhemoglobin and deoxyhemoglobin concentration changes in the cortex, while infants and young children (pictured here, a 2-year-old boy) carry out active tasks.

develop until the 3rd to 4th months of life (Braddick et al., 1980). By 2 months of age, infants in PET studies showed specific responses to face stimuli within the occipital cortex (Tzourio-Mazoyer et al., 2002). Although some functional activation thus occurs in these cortical regions before they are fully anatomically and metabolically developed, the progression of functional correlates of cognitive activity from subcortical to cortical regions is likely related to the fact that subcortical regions develop structurally before cortical regions; cognitive functions thus develop as their underlying cortical substrates mature and become functionally active.

As different regions of the cortex mature at different rates, the development of specific cognitive abilities is often associated with changing regions of functional activation over time. Changes in memory – arguably the basis of all learning and cognitive development – are good illustrations of this principle. In adults, declarative memory, or memory for facts or events, depends on a distributed network of medial temporal and cortical structures, and their intervening connections. Sensory inputs from a variety of origins converge on the hippocampus (a structure that lies deep in the medial temporal lobe) where they are bound together to create a memory trace; various cortical structures are implicated in the long-term storage of memories, and the prefrontal cortex is thought to be critical to memory retrieval (Bauer, 2013). PET studies of infants indicate that areas of the temporal lobe show peak metabolic activity by 3 months of age, then slowly decline to adult levels; in the medial temporal regions of the hippocampus, adult numbers, and densities of synapses are reached by approximately 6 months (Bauer, 2009, 2013). Accordingly, declarative memory capacities are low in very young infants, and ERP studies on 4-month-olds produce no evidence that these children differentiate between familiar and novel stimuli (Nelson and Collins, 1991). By about 6 months of age, however, many infants can remember an average of one action of a 3- or 5-step action sequence for a period of 24 h (Barr et al., 1996; Collie and Hayne, 1999), and ERP studies indicate that 8-month-olds show distinct responses to familiar vs. unfamiliar stimuli, even after infrequent exposure to the 'familiar' (Nelson and Collins, 1992). As the dentate gyrus of the hippocampus matures (showing peak synaptic density around 24 months and pruning to adult levels by 8 years of age; Seress and Ábrahám, 2008) and major frontal lobe development occurs (blood flow to this region peaks between 8 and 14 months of age (Chugani, 1994) and synapses in this region develop adult morphology around 24 months (Huttenlocher, 1979)) over a longer period, they are accompanied by changes in various aspects of declarative memory, such as encoding and retention periods. For example, 16-month-olds exhibit less immediate recall than 20-month-olds, and 12-month-olds require more learning trials to achieve the same level of recall as 18-month-olds (Bauer and Dow, 1994; Howe and Courage, 1997). In terms of long-term retrieval, by 9 months of age infants can remember single actions for up to 5 weeks and by 13–14 months of age, they may remember over delays of up to 4–6 months (Carver and Bauer, 2001). In the latter half of the second year of life, infants may remember entire 4-step action sequences for up to 12 months (Bauer et al., 2000). Improvements in encoding and lengths of recall periods then improve, albeit less dramatically, until adolescence, when the medial temporal and cortical structures and their intervening connections have reached near adult structural and functional maturity.

Over the course of infant cognitive development, brain activity also changes from being diffuse (recruiting larger or more areas) to becoming more focal (activating smaller regions with increased magnitudes; Durston and Casey, 2006). In the domain of face processing, for example, 2-month-old infants who were shown static pictures of unknown women's faces and imaged using PET, showed neural activation over a distributed network of cortical areas; these areas included the inferior temporal gyrus and the occipitotemporal sulcus, which are likely homologues of the fusiform face area in adults, as well as the left superior temporal and inferior frontal gyri, which are not recruited for face processing, but are associated with language processing in adults (Tzourio-Mazoyer et al., 2002). ERP studies of face processing also reveal that there are two distinct components of the infant ERP waveform that show sensitivity to faces (the N290 and the P400). These components are more medially distributed and smaller in amplitude than the adult face response (the N170; de Haan et al., 2002). While the infant N290 is larger to human than monkey faces by 3 months of age, this component does not differentiate between upright and inverted faces until 12 months, when its amplitude is higher in response to upright relative to inverted faces. By about 4 years of age, as a result of cortical specialization, a single adult-like N170 is observed during face processing, and the amplitude of this component continues to increase, reaching adult levels in adolescence (Nelson et al., 2006).

The change from more diffuse to more focal brain activation may reflect the functional consequences of synaptic pruning and other regressive brain maturation processes, in concert with the strengthening and fine tuning of relevant neural connections. Often, as brain activation becomes more focal over development, activation patterns may also change from being bilaterally distributed to becoming increasingly lateralized within one hemisphere of the brain. Recent advances in speech perception research provide a prime example of this phenomenon. Two- to five-day-old neonates who were played forward and backward recordings of infant-directed speech (Peña et al., 2003) or speech and music (Kotilahti et al., 2010) and imaged using fNIRS showed significant increases in total hemoglobin in the channels overlying the left and right temporal regions during forward speech in comparison to silence. The total hemoglobin increase was also significantly greater in the left compared to the right hemisphere when neonates heard forward speech as compared to reversed speech (Peña et al., 2003). In an fMRI study of 3-month-olds, similar lateralization was observed to forward vs. reversed speech in the left superior temporal and angular gyri, and significant activity was observed in the right dorsolateral prefrontal cortex in response to both types of speech stimuli in waking but not sleeping infants (Dehaene-Lambertz et al., 2002). Thus, although infants show hemispheric lateralization (a bias toward left hemisphere dominance) in speech processing from birth, this left hemisphere activity can be nonspecific, and is accompanied by significant functional activation in the right hemisphere. By about 6 months of age, however, infants imaged using fNIRS showed significant oxyhemoglobin increases in the left hemisphere, but not in

the right hemisphere, to speech in the presence of visual animations as compared to only visual stimuli (Bortfeld et al., 2009), and significant oxyhemoglobin changes in the right hemisphere to stimuli that differed in pitch (Homae et al., 2012). This developmental trajectory – with speech processing becoming more localized to regions of the left hemisphere, and pitch and prosody processing increasingly associated with right hemispheric activation as cortical specialization increases – continues through infancy and childhood into adolescence. In an fMRI study of children aged 7–18 years, activation to a verb generation task occurred in Broca's area, Wernicke's area, the cingulate gyrus, and the dorsolateral prefrontal cortex, with significant increases in lateralization and lateralized signal strength in Broca's area associated with increasing age across the participants (Holland et al., 2001).

The timing of neural responses that subserve cognitive functions also changes over development. In the aforementioned face-processing studies, in addition to ERP amplitude changes over development, researchers observed changes in the latency of ERP responses, with the general tendency for responses to occur more quickly, or to decrease in latency, as infants develop. Both the N290 and the P400 ERP deflections are so named because they occur at 290 and 400 ms, respectively, after a face is seen. These two components are the putative precursors of the adult ERP response to faces, the N170, which is observed 170 ms after a face stimulus is presented. Even before the more adult-like N170 response is observed in children, the latency of the P400 also changes over development. This component does not discriminate between upright and inverted human faces at 6 months of age, but by 12 months of age it responds to upright human faces with shorter latency than that observed in response to inverted faces (Halit et al., 2003).

Decreases in latency of neural signals might result from increased myelination throughout regions of the developing brain, as myelin increases the efficiency with which signals are transmitted along synapses, particularly over long distances, or between spatially distinct neural circuits. Increasing myelination along with the reinforcement and strengthening of neural circuits relevant to specific cognitive capacities results in enhanced structural connectivity over development. This structural connectivity increase is mirrored by an increase in functional connectivity, observed through various means, including the increasing prevalence and magnitude of EEG and resting fMRI coherence (synchronous oscillations measured over spatially distinct regions of the brain). In a study of EEG coherence changes in theta band frequencies over development, coherence increases were observed over neighboring regions (separated by 6 cm interelectrode distances) over the parietal and central- to lateral-temporal regions around 1.5 years of age, and then along the rostral caudal dimension (over 12 cm interelectrode distances) at 2.5 years of age (Thatcher, 1992). Functional connectivity continued to increase in sudden spurts, over longer ranges, and over both ipsilateral and bilateral distances as participants increased in age to 7 years. Using fMRI, Gao et al. (2009) more recently found little connectivity in 2-week-old infants, a marked increase in the percentage of connectivity and the number of regions exhibition connectivity in the brains of 1-year-olds, and a steady increase from then until 2 years of age, at which point the default network had attained adult-like connectivity. Such increases in long-range functional connectivity occur along with the aforementioned focalization of neural activity over development, so that smaller regions of increasingly specialized brain activation may be integrated. The cognitive consequences of increased functional connectivity are thus likely observed in the development of higher order cognitive processes such as visual working memory, which has shown evidence of increasing rapidly in change-preference tasks (in which infants with the working memory capacity to detect changes in visual stimuli are predicted to preferentially look at one or more of a set of displays that has changed) between 6 and 10 months of age (Perone et al., 2011).

Several other patterns of change in brain activation are observed during infancy. As cognitive abilities develop, for example, functional activation increases in the areas of the brain known to be critical for these competencies in adulthood. Bell and Fox (1997) found individual differences in EEG power in a group of 8-month-olds, such that infants who were successful at object permanence tasks showed increased EEG power over frontal and occipital regions as compared to those who were unsuccessful at the tasks. In a longitudinal study using fNIRS, increases in oxyhemoglobin were observed over the frontal cortex between the period of 5 and 12 months of age, as object permanence developed. Significant frontal activation was only observed in infants once they had attained object permanence, as compared to the previous time point in which they had not yet shown behavioral evidence of object permanence. Infants in this participant pool developed object permanence and the associated change in functional brain activation around 7 months of age (Baird et al., 2002).

In addition to changes in neural activation and cognition that occur as a result of different brain regions coming 'online' at varying rates, top-down shifts in cognitive strategy may alter the neural substrates of cognition over development. In the domain of mathematical cognition, for example, infants are able to discriminate quantities with increasing proficiency over development starting long before they begin to learn language and develop a speech-based numerical symbol system (Feigenson et al., 2004). Once language abilities start to develop and numbers are taught through a verbal symbol system, however, the substrates of numerical cognition expand to include new regions such as the left angular gyrus and perisylvian areas, which are activated during both phoneme detection and calculation tasks (Dehaene et al., 2003). Although longitudinal research tracking the neural correlates of mathematical skills over development remains to be done, recent studies using fNIRS technology have begun to chart the precursors of mathematical cognition over development. Hyde et al. (2010), for example, have demonstrated that the right parietal cortex is sensitive to discrimination of quantities in a 1:2 ratio, in infants as young as 6-months-old.

Summary and Considerations for Future Research

The first few years of life are a period of rapid cognitive development. Within 2 years of being born, children typically

develop the capacity to communicate with their parents and peers through language, to rapidly recognize and distinguish between the faces of other humans, and to remember events up to a year after they have occurred. Both structural and functional changes in the brain underlie and give rise to the cognitive developments, as well as the changes in behavior that we observe over the course of a person's lifetime; additionally and in turn, changes in behavior also bring about changes in the brain. For example, as the cortex becomes increasingly active and specialized, infants develop the ability to hear and then produce an array of distinct sounds; as children increasingly produce and listen to some speech sounds and not others though, those neural circuits corresponding to the sounds that they practice become stronger, both functionally (increasingly efficient neural signal transmission) and anatomically (increasing synaptic density, changes in the numbers of dendrites), and those circuits associated with sounds that they do not practice weaken (as neuronal signaling slows at these synapses) and disappear (as neurons die naturally by apoptosis). In understanding the ontogeny of human cognition then, it is necessary to take a dynamic, developmental approach that focuses on the trajectories that brain activity and behavior take over time, rather than to assume that the adult brain is a template that guides brain and cognitive development over the life span. Such a developmental focus has important implications for the design and interpretation of future research into human cognition, as well as profound practical implications for the ways in which educational and therapeutic programs are developed for individuals at different stages of life.

Increasingly sophisticated and diverse imaging technologies are now being used to elucidate the substrates of cognition and the changes therein in infants and young children. Such technologies are particularly useful for understanding development during infancy, when the precursors of various cognitive capacities are being formed, but cannot be directly observed in behavior. Neuroimaging has been used to show, for example, that typically developing infants can discriminate even closely related languages from their native languages by 4 or 5 months of age, long before they utter their first words. These methods may thus enable researchers and clinicians to monitor the development of typical abilities in infants and to identify those at risk for difficulties or impairments long before they might have been able to do so behaviorally. As research into the cognitive development of infants and young children moves forward, neuroimaging may become an important tool for facilitating early diagnosis and enabling early intervention for those children at risk of developmental delays or deficits.

Relatedly, neuroimaging may enable researchers to illuminate the extent to which certain cognitive capacities are experience-dependent and perhaps more malleable, or experience-independent, and thus unlikely to be affected by interventions. For example, although behavioral data indicate that humans are born with a proclivity for human faces, ERP studies have shown that the neural bases of these responses to faces are distinct from those used by adults, and may develop for the faces of other species to which infants are given increased exposure (Nelson et al., 2006). In the case of a child who is at increased risk of exhibiting face processing deficits or who does not show typical patterns of orienting to faces then, these studies indicate a potential role for human intervention – perhaps by increased exposure to relevant faces and/or the use of specific ERP components to monitor this ability over development – in improving the child's developmental outcomes. Understanding those areas of brain and cognitive development that appear to be experience-independent and thus less changeable by human intervention is just as important, in preventing the expenditure of time and money on educational or therapeutic programs that may ultimately prove fruitless.

In addition to experience-dependence and -independence, caregivers and scholars of human cognitive development are also invested in determining the relative role of genetic and environmental influences on the emergence of cognitive abilities. Such distinctions are notoriously difficult to tease apart, because of the reciprocal relationship that exists between the brain and behavior. Although we often talk about the neural substrates underlying behavior, it is important to keep in mind that behavior – or one's environment – in turn, may influence aspects of brain structure and function, even at the level of the genes that guide these processes. While studies of this nature are currently conducted using cross-rearing designs in animal models, experimental designs involving identical twins, or rarer foster care and adoption studies in humans, the application of infant neuroimaging techniques to the field of 'transcultural neuroimaging' may provide an additional means of investigating the relative roles of the brain and the environment in human cognitive development. In the emerging field of transcultural neuroimaging, studies are designed to directly compare the neural correlates of specific behaviors and functions in two or more participant groups from separate cultures. Here, culture may be defined in a number of ways depending on the aims of the study – from as broadly as members of Western and non-Western cultures, to as narrowly as individuals who share identical geographies and ethnicities, but are members of different religious groups (Han and Northoff, 2008). In an interesting study using this approach, Gutchess et al. (2006), found that the neural substrates of object processing differed between Chinese and American participants in ways that paralleled the semantics of their native languages. If extended downward to infant populations, it may be possible to distinguish whether the early neural correlates of these differences existed from birth, or developed from common neural precursors, diverging only later, upon exposure to culturally specific environmental inputs.

Although the last decade of research has produced impressive advances in our understanding of the neural mechanisms of typical human cognitive development from infancy, most of these studies analyze data at the group level, and report measures of brain and cognitive development on average in the population, rather than on a more individualized basis. This trend is in part a limitation inherent to many of the imaging modalities and analytic methods currently available for investigating infants, which derive the power necessary to make statistically significant claims from large sample sizes. Average population measurements, however, run the risk of masking tremendous variation in typically developing populations, and particularly characteristic of infant populations. As such, future

research into the neural mechanisms of cognitive development in infants should employ designs that enable findings to be interpreted on both a group and individual level, and an emphasis should be placed on the use and development of imaging technologies that enable visualization and analysis of individual-level data. In addition to more accurately representing the range of neural and behavioral development inherent in typical populations, studies that relate quantitative measures of structural or functional brain activity to individual differences in cognitive performance may also provide stronger evidence than is possible through group-level correlational studies, for the role of particular neural mechanisms in the development of behavior.

Abstract

Cognitive development has yielded many findings with implications for improving classroom instruction and student learning. Improving learning in mathematics is a priority for the United States. This article describes stumbling blocks that preclude children from showing optimal learning and generalization of mathematics skills including misconceptions about fractions and features of equations, like the equals sign. After identifying these learning challenges, fruitful interventions, such as 'just-in-time' feedback, that have improved learning outcomes are described. The article concludes with information about individual differences in stumbling blocks and the effectiveness of interventions.

The field of cognitive development has yielded many findings with implications for improving classroom instruction and student learning. Improving learning in mathematics is a priority for the United States: "International and domestic comparisons show that American students have not been succeeding in the mathematical part of their education at anything like a level expected of an international leader. Particularly disturbing is the consistency of findings that American students achieve in mathematics at a mediocre level by comparison to peers worldwide." (NMAP, 2008: p. xii).

Results from a recent study that linked findings from the 'Nation's Report Card,' the National Assessment of Educational Progress, and the Trends in International Mathematics and Science Study showed that six US states performed below the international average in mathematics (National Center for Education Statistics, n.d.). The National Mathematics Advisory Panel (NMAP, 2008: p. xii) further points out that, "A strong grounding in high school mathematics through Algebra II or higher correlates powerfully with access to college, graduation from college, and earning in the top quartile of income from employment." In the following sections, several barriers that impede optimal student learning in mathematics are identified and successful interventions are documented.

First stumbling blocks that preclude children from showing optimal learning and generalization of mathematics skills are described. Research on children's misconceptions about fractions and features of equations, like negative signs, is summarized. Then, the article focuses on instances where 'practice makes imperfect' because a faulty mental set gets entrenched. Finally, the authors detail how a common teaching practice – providing students with concrete instead of abstract examples – can introduce a barrier to generalization.

After these learning challenges are identified, fruitful interventions that have helped students overcome adversities are described. For example, the authors detail the ways targeted explicit and implicit feedback has improved children's estimation abilities and how students' algebraic word problem-solving abilities were improved when they viewed worked examples interleaved with problems they needed to solve. Additionally, promising findings from fun, gamelike interventions that have brought low-income students' numerical understanding up to par with their middle-income peers, are discussed. Finally, how stereotype threat has been successfully combatted when students receive lessons reminding them that intelligence is malleable is described.

The last section concludes with information about individual differences in stumbling blocks and the effectiveness of interventions. The authors focus on individual differences in use of addition strategies and cross-cultural differences in mathematics learning, as well as factors that influence the effectiveness of a well-established intervention – worked examples.

Stumbling Blocks that Preclude Optimal Learning in Mathematics

Misconceptions in Learning

The National Mathematics Advisory Panel (2008: p. 18) noted, "The most important foundational skill not presently developed appears to be proficiency with fractions (including decimals, percent, and negative fractions). The teaching of fractions must be acknowledged as critically important and improved before an increase in student achievement in Algebra can be expected." Subsequent research has confirmed this assertion, demonstrating that fraction knowledge is predictive of Algebra readiness, performance, and learning (Booth and Newton, 2012; Booth et al., 2014). In this section, common misconceptions that impede children's fractions understanding (for a recent review, see Siegler et al., 2013) and algebraic problem-solving abilities are discussed.

Both children and adults struggle to accurately represent the value of fractions (Opfer and DeVries, 2008; Thompson and Opfer, 2008). Siegler et al. (2011) hypothesized that faulty fractions understanding stems from overextending automatic processing of whole numbers to all other numbers, including fractions. However, characteristic features (Keil and Batterman, 1984) of whole numbers (i.e., that whole numbers have unique successors, include a finite number of entities within any given interval, can be expressed as a single symbol, etc.) are not defining features of all numbers. For example, there are an infinite number of fractions between the interval 0 and 1. However, the defining feature of all numbers is their possession of magnitudes that can be represented on a number line. Siegler

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92146-9

et al. (2011) found that sixth and eighth graders who transformed fractions into easier-to-handle formats (e.g., 1/3 is a small number because it is less than half) and subjectively segmented the number line (e.g., 2.5 is the halfway point on a 0–5 number line) made more accurate fraction estimates than children who did not use such effective strategies. As with whole numbers, tasks tapping fractions magnitude understanding correlated strongly with standardized achievement test and fractions arithmetic performance.

Siegler and Thompson (2014) found that experimenter-imposed landmarks can help, hinder, or fail to impact fractions estimates. Some objective landmarks (e.g., 0, 1, 2, 3, 4, and 5 in the 0–5 range) promote encoding of structurally important features of numbers and use of relevant strategies. For example, use of the mixed number strategy, translating 18/7 into 2 and 4/7, and placing this mixed number between 2 and 3 on a 0–5 number line, resulted in accurate number line estimates. However, other objective landmarks hindered students' estimation accuracy by promoting encodings and strategies that were not structurally important. For instance, children treated numerators and denominators as independent whole numbers when they estimated the location of fractions on a number line with quintile landmarks (0, 1/5, 2/5, 3/5, 4/5, and 1). A child using the independent components strategy might incorrectly match the numerator of the to-be-estimated fraction, 3/8, to the landmark with the matching numerator, 3/5. Other landmarks, like 1/2 in the 0–1 range, were redundant with children's processing, and these objective landmarks did not prove more or less advantageous than a number line without objective landmarks. For example, children often subjectively segmented 0–1 lines without objective landmarks at the halfway point and considered whether the to-be-estimated fraction was greater than or less than 1/2.

Middle school students also hold persistent misconceptions about critical features of algebraic equations (Booth and Koedinger, 2008). For instance, students lack conceptual understanding of the equals sign and believe that it means that an operation should be performed, or an answer should be found, rather than exhibit an understanding that one side of the equation is equivalent to the other side. Booth and Koedinger (2008) found that students often perform an operation on one side of the equation, but fail to carry out the operation on the other side. Another common misconception that impacts algebraic problem solving is the meaning of negative signs. This misconception was best illustrated in an in-depth case study where one student claimed that $-4x + 3$, $4x + 3$, and $4x - 3$ were equivalent expressions. This student failed to realize that the negative sign modifies the term to which it is tied and moving the negative sign changes the meaning of the equation. A more recent study revealed that students with these types of misconceptions not only have difficulty solving equations but also fail to encode the equations correctly (Booth and Davenport, 2013).

In summary, children maintain widespread misconceptions about mathematics. For instance, children overextend what they know about whole numbers and mistakenly assume these characteristic features are defining features of all numbers, including fractions. Also, children misunderstand the meaning of the equals and negative sign; these misconceptions are often detrimental to children's Algebra performance (**Table 1**).

Table 1 Summary of misconceptions in learning

Finding	*Example*
Children overextend what they know about whole numbers to fractions.	When asked to estimate 3/19 on a 0–1 number line, a child may place this fraction closer to 1 than to 0 and provide the explanation that 19 is a big number.
Children misunderstand the meaning of the equals sign and negative sign.	Children often believe that the equals sign means to carry out an operation, and do not realize that it means that one side of the equation should be equivalent to the other. Further, children do not realize that the negative sign is tied to an algebraic term, and moving the negative sign modifies the entire meaning of the equation.

Mindlessness and Automaticity

The old adage, 'practice makes perfect,' speaks to the beneficial impact of automaticity. However, research reviewed in this section suggests that automaticity can be detrimental in some learning contexts, like mathematical equivalence problems, but children's gesture–speech mismatches can identify those children on the brink of a breakthrough in understanding.

Children are drilled on simple arithmetic problems of the form: $2 + 3 + 4 =$ ___. This extensive practice may lead children to misinterpret the meaning of the equals sign (e.g., carry out an operation). Later, when children are asked to find the answer to a problem like $2 + 3 + 4 =$ ___ $+ 4$, they may mistakenly answer 9, because they added all numbers on the left side of the equation, or 13, because they added all numbers on both sides of the equation. Interestingly, U-shaped development is evident when 7-year-olds outperform 9-year-olds on equivalence problems (McNeil, 2007). Older children do worse on these equivalence problems because of their resistance to change; they have practiced the simple equations to mastery and this extensive practice makes it very difficult to inhibit adding everything to the left of the equals sign and placing that number in the blank on the right side of the equation. Subsequent research (McNeil, 2008) found that children who practiced typical problems ($15 + 13 = 28$) produced fewer correct responses on a follow-up equation-solving task ($5 + 4 + 7 =$ ___ $+ 3$) than did those children who completed training on atypical problems ($28 = 28$) that focused on the conceptual meaning of the equals sign (e.g., the left and right sides of the equation must be equivalent). McNeil suggested the results were a product of 'mindlessness' whereby students relied on strategies that had worked for them in the past but failed to recognize that these strategies were not appropriate for the task at hand.

Children on the cusp of learning often show variability in their performance (Siegler, 1994). This variability is evidenced in gesture–speech mismatches on equivalence problems (Perry et al., 1988). For instance, even though a child may provide the incorrect answer of 9 on the problem $2 + 3 + 4 =$ ___ $+ 4$, a gesture–speech mismatch may occur when the same child simultaneously points to the 2 and 3 on the left of the equation and the blank on the right of the equation indicating she has an implicit understanding that 2

and 3 can be added together and correctly inserted in the blank on the right (Goldin-Meadow, 2001).

Similarly, participants may rely on inappropriate mental sets (Luchins and Luchins, 1950), or *Einstellungsmuster*, when they attempt to transfer what they have learned about numbers from one context to the next. Opfer and Thompson (2008) tested whether uncorrected practice on a pretest might result in entrenched, inappropriate numerical representations. One group of participants completed a number categorization pretest in which children were asked to identify which category – really small, small, medium, big, or really big – best described particular numbers in the 0–1000 range, then received training on the correct locations of numbers on number lines, and finally completed an identical number categorization posttest. Other children received training on a number line estimation task and then completed a number categorization posttest. The group that completed a pretest did not receive any feedback on the correctness of their category judgments, so they did not know that they were practicing an inappropriate representation for the task. Even when they subsequently received feedback on a related estimation task during training, participants failed to transfer the more appropriate representation to the categorization posttest. That is, when these pretested participants completed a posttest identical to their uncorrected pretest, their initial, albeit inaccurate, representation was activated and led to diminished transfer of learning.

In summary, at times 'practice makes imperfect' when children's numerical representations become entrenched with extensive practice and children mistakenly generalize an overpracticed representation to a context in which it is not relevant (**Table 2**).

Table 2 Summary of mindlessness and automaticity

Finding	*Example*
Children make mistakes on mathematics equivalence problems because they cannot inhibit their overly practiced responses and mindlessly rely on strategies that are not appropriate for the task at hand.	Children mistakenly fill in the blank with 9 or 13 in the following problem: $2 + 3 + 4 = ___ + 4$.
Children show gesture–speech mismatches in mathematics equivalence problems indicating that they have some implicit understanding of how to solve the problem even if they cannot explicitly answer it.	Children verbally provide the wrong answer in the above equivalence problem, but they may simultaneously point to the 2 and 3 on the left side of the equation and the blank on the right side of the equation.
Inappropriate representations can become entrenched with practice.	Those children who practiced an inappropriate representation while completing an unsupervised numeric category judgment pretest failed to transfer a newly learned representation to an equivalent numeric categorization posttest.

Concrete versus Abstract Instantiations

Instructors frequently provide students with concrete examples to make abstract concepts more accessible and meaningful. For instance, the Institute of Education Sciences (IES) Fractions Practice Guide (Siegler et al., 2010) suggests that teachers should build on their students' naive understanding of sharing and proportionality to promote early fractions understanding. However, could there be instances in which concrete examples hinder learning and transfer to new situations? In this section, the authors summarize views in favor of the use of concrete examples, such as Piaget's constructivist view of knowledge acquisition, and the recommendation by the National Council of Teachers of Mathematics to incorporate concrete examples into the curriculum. Then, the authors summarize research that suggests concrete instantiations may inhibit optimal transfer, and usefulness of concrete examples might depend on the skill level of learners.

Piaget's (1960) theory of cognitive development maintains that active manipulation of physical objects is important for children's learning in the concrete operational stage of development; from these experiences, children are thought to be able to garner more abstract concepts (Kamii, 1974). Consistent with this, manipulatives, or concrete objects designed to help children learn mathematics (Uttal et al., 1997), are used widely in elementary school classrooms. However, research on the effectiveness of using manipulatives (e.g., counters for simple arithmetic, Dienes blocks for place value) or other concrete instantiations (hundreds squares for arithmetic with larger numbers, a pizza cut into multiple equivalent pieces to represent fractions) in the classroom has had mixed results, with some findings asserting they are beneficial (e.g., Sowell, 1989) and others suggesting no value added (e.g., Friedman, 1978).

The idea of bridging instruction from concrete to abstract instantiations does not end in elementary school, and the technique is supported by a number of empirical studies (e.g., Moreno and Mayer, 1999; Goldstone and Son, 2005). In fact, the NCTM (2000) recommends that teachers include multiple forms of representations – including concrete examples – when teaching mathematical concepts.

However, recent research calls into question whether concrete instantiations best support student learning. Undergraduate students, who were given either concrete or symbolic (abstract) representations, learned basic properties of number equally, but those studying abstract representations displayed improved transfer to novel problem-solving contexts (Kaminski et al., 2008). This study suggests that concrete instantiations may constrain learners' understanding of a concept to the presented context, thus hindering transfer.

Similarly, diagrams are often successfully used to facilitate understanding of text (Mayer, 2005), and combining them with algebraic word problems supports problem-solving performance for older and higher ability middle school students (Booth and Koedinger, 2012). However, the same representations may actually hinder younger, lower ability students, who show greater problem-solving success with textual problems alone (Booth and Koedinger, 2012). Younger and lower ability students are often unable to correctly map

diagram components to the relevant pieces of text and become increasingly confused by the problems.

In summary, not every student will universally reap the benefits of concrete examples. These and other studies caution that the relative benefit of concrete and abstract representations may vary with characteristics of the user, the representation, or the goals of the task (Ainsworth, 2006; Larkin and Simon, 1987) (**Table 3**).

Table 3 Summary of concrete versus abstract instantiations

Finding	*Example*
Adults may learn better from abstract instantiations than concrete ones.	Undergraduate students learning about number properties from abstract instantiations were better able to translate their knowledge to solve real-world problems.
Although much emphasis is placed on using concrete instantiations to help children learn, children do not always learn better from concrete instantiations.	When solving algebraic word problems, younger middle school students and those with less prior knowledge succeed more when a corresponding diagram is not provided.

Interventions that Improve Mathematics Learning Outcomes

Explicit and Implicit Feedback

Is it possible for children to learn as much from direct instruction as from discovery learning? In this section, the relative benefits of explicit and implicit feedback to improve children's estimation skills are investigated.

According to Piaget's (1970: p. 715) constructivist approach, "each time one prematurely teaches a child something he could have discovered for himself, that child is kept from inventing it and consequently from understanding it completely." Contrary to Piaget's view, Klahr and Nigam (2004) claim, 'what is learned is more important than how it was taught.' For instance, students who received direct instruction and answered questions that probed their knowledge were more successful at learning to create unconfounded experiments by using the Control of Variables Strategy (CVS, Chen and Klahr, 1999) than peers who attempted to discover this principle on their own (p. 662). Most importantly, direct instruction allowed children to generalize the CVS strategy to analogous contexts.

The question remains, however, are explicit and implicit direct instruction equally effective at bringing about conceptual change and facilitating problem-solving skill? Research investigating children's and adults' analogical problem solving suggests that providing explicit hints or reminding participants to draw parallels between key components of isomorphic problems leads to improved accuracy (Gick and Holyoak, 1980; Brown et al., 1986). NMAP (2008) recommended that it is particularly important for low-achieving students and children diagnosed with mathematics disabilities to receive frequent direct instruction. This direct instruction might take the form of explicit feedback about the accuracy of students' performance, discussion of the appropriate strategies for solving problems, and encouragement to ask and answer questions and talk aloud as students attempt to solve mathematics problems. Participants can also benefit from implicit instruction when various example problems are aligned to facilitate surface-level comparisons (Kotovsky and Gentner, 1996). This comparison process allows participants to move beyond perceptual similarities and recognize commonalities at a more abstract, conceptual level (Gentner et al., 2003).

In the domain of numerical cognition, children also benefit from explicit and implicit instruction aimed at improving their estimation abilities. Children and adults know and use multiple representations (e.g., linear and logarithmic) depending on the numerical context at hand (Siegler and Opfer, 2003; Siegler et al., 2009; see Barth and Paladino, 2011 for an opposing view and Opfer et al., 2011 for a meta-analysis). That is, although second graders accurately estimated the location of 75 on a 0–100 number line, these same children tended to wildly overestimate the location of 75 on a 0–1000 number line. This pattern of overestimation of relatively small numbers and failure to differentiate the locations of relatively large numbers characterizes the logarithmic representation. With increasing age, children exhibit a logarithmic-to-linear shift as they begin producing more accurate, adultlike, estimates that are equally spaced across the number line. This conceptual change across development unfolds in a piecemeal manner; with age, children gradually scale up their linear representation from smaller to larger numerical contexts (Siegler and Opfer, 2003; Siegler and Booth, 2004; Siegler et al., 2009, 2010).

Children who produce more linear estimates show better performance on standardized achievement tests (Booth and Siegler, 2006); they also display greater accuracy in recalling numerical information presented in meaningful vignettes (Thompson and Siegler, 2010; Thompson and Opfer, 2011) and answers to novel arithmetic problems (Booth and Siegler, 2008; Siegler and Ramani, 2009). These associations speak to the importance of developing a linear representation of numerical magnitudes, and have prompted investigation of the usefulness of targeted interventions to improve children's estimation abilities. To this end, Opfer and Siegler (2007) provided children with feedback about their estimates in the 0–1000 range. In this intervention, children learned that they had greatly overestimated the location of 150, the maximally discrepant point between a logarithmic and linear function forced to pass through 0 and 1000. On receiving one trial of corrective feedback, children abruptly adopted a linear representation as they estimated the location of subsequent numbers in the 0–1000 range.

However, explicit feedback does not always lead to positive learning outcomes. Children who received explicit feedback on a whole number estimation task inappropriately transferred their newly learned linear representation to an estimation task with unit fractions (e.g., those with a numerator of 1: Opfer and DeVries, 2008; Thompson and Opfer, 2008). Both children and adults failed to represent the fractional magnitudes (e.g., 1/60 is a very small number) and instead only represented the denominators as independent whole numbers (e.g., 60). While use of a linear representation optimizes accuracy when estimating whole numbers (e.g., 60 is located closer to 1 than to 1440), the linear representation does not optimize accuracy when used to estimate the location of unit fractions (e.g., 1/60 placed nearer to 1/1 than to 1/1440). This cognitive illusion

likely stems from children's and adults' familiarity and extensive practice with whole numbers.

Implicit feedback, like explicit feedback, can cause representational change. Thompson and Opfer (2010) used progressive alignment methodology (Kotovsky and Gentner, 1996) to highlight the underlying structural similarity of magnitudes within the numerical decimal system. A small, familiar range (0–100) was aligned with large, unfamiliar ranges (0–1000, 0–10 000, and 0–100 000) prompting second graders to draw comparisons across surface-level features (e.g., number of zeros in the 0–100 and 0–1000 ranges). These comparisons highlighted an analogy (e.g., 15:100::150:1000) that could be drawn between small and large ranges and was not as evident to children who did not observe the alignment of small and large ranges. The progressive alignment group produced more accurate estimates in large numerical ranges (0–10 000 and 0–100 000); this representational change persisted on a posttest without alignment.

In summary, numerical cognition research suggests that children's estimation performance can be improved with explicit as well as implicit feedback, and this targeted experience prompts children to exhibit adultlike estimation abilities. However, under some circumstances children may inappropriately overgeneralize corrective feedback (**Table 4**).

Table 4 Summary of explicit and implicit feedback

Finding	*Example*
Children's numerical representations have been improved via explicit feedback.	Children who produced an inaccurate, logarithmic series of estimates abruptly switched to producing an accurate, linear series of estimates after receiving corrective feedback on the location of 150 in the 0–1000 numeric range.
Children's numerical representations have been improved via implicit feedback.	Children who saw 0–100 number lines aligned with 0–1000 number lines learned to produce a more accurate series of estimates by drawing a relevant analogy (e.g., 15:100::150:1000).

Learning from Worked Examples

Attempting to solve long strings of problems is not the optimal method for having students hone their problem-solving skills. While practicing, students should also study examples that illustrate how to solve problems (Sweller and Cooper, 1985; Sweller, 1999). In this section, how examples have been used to target critical skills, such as procedural fluency, conceptual understanding, and problem-solving flexibility, is summarized.

Using examples in the traditionally suggested way, by replacing approximately half of practice problems in a set with fully worked-out examples for students to study (Sweller, 1999), improves students' procedural knowledge, largely because it reduces students' cognitive load and allows them to focus on learning the steps, and underlying meaning of those steps, necessary to understand a problem (Zhu and Simon, 1987; Sweller, 1999). Scaffolding has also been used to improve students' procedural fluency by having students study complete examples and then gradually fading the completeness of the examples throughout the practice session (Renkl et al., 2000).

Another line of research, focused more on conceptual understanding, suggests that students should be asked to *explain* examples, not just study them. Such self-explanation is thought to improve learning by forcing students to make their newly acquired concepts explicit (Chi, 2000; Roy and Chi, 2005). While most worked-example research focuses on the use of correct examples, recent work suggests that a combination of correct and incorrect examples (with prompts for self-explanation) can be even more effective (Siegler, 2002; Rittle-Johnson, 2006; Siegler and Chen, 2008). Explaining errors can be beneficial because it helps struggling students accept that they have chosen incorrect procedures and realize why those strategies are inappropriate. For instance, consider a student attempting to solve $4x - 3 = 6$ by subtracting 3 from both sides, and ending up with $4x = 3$. When the student explains how the procedure used led to the incorrect answer, it forces the student to notice that the negative sign before the 3 in $4x - 3 = 6$ is the feature that makes the procedure inappropriate. Consistent with this assertion, explaining incorrect examples has been shown to lead to improvements in conceptual understanding in Algebra (Booth et al., 2013).

Examples can also be used to improve students' flexibility in problem solving, or their ability to recognize more than one way to solve a problem and choose the most effective one (Star and Seifert, 2006; Rittle-Johnson and Star, 2007). For this purpose, directly comparing and contrasting multiple examples of how to correctly solve a particular problem can be more effective than studying such examples sequentially (Rittle-Johnson and Star, 2007). While introduction of multiple solution methods has been shown to benefit even struggling students (Newton et al., 2010), the contrasting cases method may be most useful for students who already have achieved an adequate level of prior knowledge in the domain (Rittle-Johnson et al., 2009).

In summary, interleaving worked examples with practice problems improves children's procedural understanding of the steps necessary to solve the problems, explaining correct and incorrect answers in worked examples improves children's underlying conceptual knowledge, and comparing and contrasting simultaneously presented worked examples can show students that multiple strategies can be used to solve given problems (**Table 5**).

Table 5 Summary of learning from worked examples

Finding	*Example*
Studying worked examples promotes students' procedural learning.	Students who study worked examples during their practice sessions learn more of the content or learn the same amount faster.
Explaining worked examples, especially incorrect ones, promotes students' conceptual understanding.	Students who explained common errors for solving algebraic equations showed greater gain in conceptual knowledge of the features in the problems.
Comparing and contrasting worked examples promotes flexibility in problem solving.	Studying contrasting cases of two ways to solve the same problem leads students to recognize multiple solution paths and adopt more efficient solution methods.

Learning via Games and Cognitive Tutors

Academic engagement is the degree to which students are attentive, interested, and invested in learning (Marks, 2000). Not surprisingly, student engagement is positively related to achievement; a lack of engagement is typically detrimental to learning (Finn, 1989). Much research has been focused on finding ways to make instruction more engaging to improve learning in a variety of domains. In this section, learning gains resulting from children engaging with numerical board games and Cognitive Tutors are reviewed.

One of the ways researchers have tried to increase engagement in mathematics is to use games to introduce and strengthen core math skills. For example, the Number Worlds' curriculum uses interactive games to strengthen preschoolers' number sense by providing experience with different facets of number (e.g., quantities, counting, formal notation) and opportunities to understand the relations between those facets (Griffin, 2004; Griffin et al., 1994). Use of this curriculum has improved learning and achievement for at-risk children; its use in the RightStart program led to gains that lasted a year (Griffin et al., 1994). More recently, research by Siegler and colleagues (Siegler and Ramani, 2008, 2009; Ramani and Siegler, 2008, 2011) has shown that children from low-income homes can catch up with middle-income age mates after playing a linearly spaced numeric board game, akin to Chutes and Ladders, for about an hour. This experience is thought to reinforce numerical magnitude understanding across multiple modalities (visual, auditory, tactile, etc.), and the resulting improvements in numerical magnitudes' understanding remain evident more than 2 months later. Given the mounting evidence for the importance of magnitude knowledge for learning in math (e.g., Booth and Siegler, 2008), the use of games as instructional tools has the potential to help young children gain the foundations necessary for later success in mathematics.

Another instructional method that has been used to increase student engagement and learning is the use of intelligent tutors to provide individualized instruction for students (Anderson et al., 1985). One such tool, the Cognitive Tutor, was originally developed to improve student learning in Algebra (Koedinger et al., 1997), but has since been developed for other courses, including Pre-Algebra, Algebra II, and Geometry (see www.carnegielearning.com). The Cognitive Tutor allows students to work through Algebra I content at their own pace while providing just-in-time feedback and hints as needed during practice sessions. For example, if a student chooses to begin solving the problem $3x - 5 = 1$ by subtracting 5 from both sides, the step will turn red and a pop-up message may appear, pointing out that the 5 is already negative, so it should not be subtracted from both sides. The Tutor also tracks student learning across problems, monitoring the student's strengths and weaknesses and providing appropriate types of problems until the student achieves mastery on necessary skills (Koedinger et al., 1997). Evidence suggests this approach is superior to traditional methods of mathematics instruction and practice (Ritter et al., 2007), and has been identified by the What Works Clearinghouse (2009) as a potentially effective method for middle school math instruction.

In summary, researchers have created fun ways for children to engage in mathematics curricula via games and Cognitive Tutors. Numerical board game interventions bring low-socioeconomic status (SES) children's numerical understanding up to par with that of their middle-income age mates. Further, Cognitive Tutor's 'just-in-time' feedback has been proved to be more effective than traditional classroom lessons where individualized and targeted feedback is not always present (**Table 6**).

Table 6 Summary of learning via games and cognitive tutors

Finding	*Example*
Numerical board games enhance children's numerical understanding.	Playing a numerical board game for just 1 h closed the gap in numerical knowledge between low-SES and middle-SES children.
Individualized instruction from intelligent tutors promotes learning.	Algebra students enrolled in a Cognitive Tutor Algebra 1 course learn more over the course of the year than students in traditional classrooms.

Interventions that Combat Stereotype Threat

Most of the factors impacting learning discussed here are cognitive aspects of the learner and interventions aimed at facilitating student comprehension of content material. However, psychosocial factors are also important in predicting whether an individual will learn and succeed. In this section, we detail ways stereotype threat may substantially impact student performance, especially in mathematics and other Science, Technology, Engineering, and Mathematics (STEM) domains (NMAP, 2008).

Research suggests that stereotype threat, or the increased anxiety and decreased performance by members of groups, which are stereotypically considered to perform poorly in a given domain, is induced when the individual's race (or gender, SES, etc.) is made salient just prior to assessment (Steele and Aronson, 1995; Croizet and Claire, 1998). However, more recent research suggests that stereotype threat hinders learning, even though the characteristic is not made particularly salient, and may be the default mode for stereotyped individuals when approaching mathematics tasks (Good et al., 2008).

Thus, reduction of stereotype threat may not be as easy as ensuring that students are not reminded of stereotypes. However, it can be combatted through measures to change the way students think about themselves and their potential to succeed. For example, one type of intervention focuses on helping students understand that intelligence is malleable – that individuals do not have a fixed amount of intelligence. One reason that stereotype threat may be detrimental to students is that it makes them feel that their innate abilities are being questioned. Students who believe that these innate abilities are limited and fixed are often anxious about being assessed on those abilities, and may become less motivated to succeed compared with students who believe intelligence

can be improved (Blackwell et al., 2007). Explicitly encouraging students to believe that intelligence is malleable can lead to improved standardized test scores (Good et al., 2003) and ease the transition to middle school (Blackwell et al., 2007).

Other interventions capitalize on the idea that a sense of belonging is necessary for success in a domain (Steele, 1997), and attempt to counteract the very message conveyed in stereotypes – that members of the stereotyped group simply do not belong in that domain (Steele, 1997). Convincing students that anyone can belong in mathematics classes, not just those who are typically expected to be successful at math, can have positive effects on students' motivation, engagement, and achievement (Good et al., 2012).

In summary, some initial interventions aimed at eradicating the effects of stereotype threat have been successful. These interventions aimed to show students that intelligence is malleable and to convince them that all students belong in and can succeed in mathematics classes (**Table 7**).

Table 7 Summary of interventions that combat stereotype threat

Finding	*Example*
For students in underrepresented minority groups, belief in the malleability of intelligence is important for achievement.	Teaching students that working hard can increase one's intelligence in math led to improvements in math achievement, especially in middle school.
For students in underrepresented minority groups, a feeling of belonging in a class or domain is important for achievement.	Convincing students that anyone can belong in math class led to improvements in math achievement, as well as in students' engagement and motivation to succeed.

Mathematical Stumbling Blocks and Effective Interventions May Differ from Student to Student

Individual Differences in Learning Mathematics

Not every child solves every mathematics problem in the same way on every trial in every context. In this section, individual differences in learning mathematics are discussed including cross-cultural differences in estimation, memory, and understanding of fractions, and strategy use in basic arithmetic.

Children in the United States lag behind their East Asian peers in many mathematical tasks. Research investigating what underlies this learning gap has shown that even before Chinese children receive formal schooling, they already outperform their US peers on counting and arithmetic tasks (Geary et al., 1993; Geary et al., 1996), likely because Chinese parents provide their preschoolers with extensive practice on these skills. Interestingly, Chinese kindergartners not only excelled at a practiced task, arithmetic of single-digit numbers, but also at an unpracticed task, estimating the location of numbers in the 0–100 range (Siegler and Mu, 2008). For both US and Chinese children, performance on the arithmetic and estimation tasks was strongly correlated. Siegler and Mu (2008) hypothesized that Chinese children received greater practice with counting fingers and sets of objects and this led to the accumulation of kinesthetic, visual, verbal, and temporal cues that mutually reinforced the magnitudes of numbers. Further, Chinese children tested early in the academic year were better able to identify Arabic numerals and recall and recognize numbers than their US peers (Thompson et al., unpublished data). US children tested at the end of their kindergarten year performed equivalently to the early year Chinese children on estimation, numeral identification, recall, and recognition. Basic memory abilities cannot explain the early year differences, as Chinese and US children recalled a list of words equally well.

Can cross-cultural differences in fractions understanding be explained by the hypothesis of linguistic determinism? Miura et al. (1999) claimed that the transparency of part–whole relations in Korean fractions names (e.g., of four parts, one) accounted for Korean children's optimal performance on a fractions identification task. However, Paik and Mix (2003) showed that neither Korean nor US children performed at above chance levels when particular foils were included. That is, if children were asked to choose a visual representation of 2/3, both groups were likely to choose incorrectly on the basis of the independent components of the fraction (2 parts shaded dark and 3 parts shaded light instead of 2 parts shaded dark and one part shaded light). However, when these independent component foils were not included, US children who received English language translations of the part–whole relations actually outperformed Korean children on the fractions identification task, likely because the Korean children were not as familiar with the formal term (jo-gak) for parts. Subsequent work by Mix and Paik (2008) showed that when a more familiar word for parts (boon) was used for the Korean translation, Korean children made accurate fractions identifications.

Individual differences are present in arithmetic performance, too. Children use multiple strategies to solve simple addition problems (Siegler and Shrager, 1984), choosing among the strategies in adaptive ways (Siegler, 1996). For example, while retrieval of simple addition facts often leads to the most accurate and least time-consuming responses, sometimes children use less adaptive problem-solving strategies, such as counting on their fingers, counting from the largest addend, or decomposing the problems into more manageable forms.

Siegler (1988) highlighted individual differences in first graders' arithmetic performance noting that students could be characterized as 'good,' 'not so good,' and 'perfectionists.' Good students made quicker and more accurate responses, performed better on standardized achievement tests, and showed more mastery of retrieval and other backup addition strategies than did not-so-good students. Interestingly, perfectionists were very accurate and did well on standardized achievement tests; however, they only used retrieval when they were very sure of their answers and often reverted to less efficient backup strategies to answer problems when they were less confident. Perfectionists effectively retrieved answers, although they used the strategy less often than did not-so-good students. More recent research has shown that children diagnosed with mathematical disabilities

knew fewer addition facts and executed addition strategies less effectively (e.g., committed more retrieval errors) than did typically achieving children (Geary et al., 2007).

In summary, significant cross-cultural differences exist in mathematics, at least in part because of varied amounts of practice with counting and arithmetic. Even individual children in the United States know and use many different strategies for solving simple arithmetic problems. Students do not always choose the most optimal strategy to solve a problem; this is especially true for children diagnosed with a mathematical disability (Table 8).

Table 8 Summary of individual differences in learning mathematics

Finding	*Example*
Cross-cultural differences in whole numbers understanding exist.	Chinese children produce more accurate estimates in the 0–100 range and remember numbers within this range more accurately, too.
Cross-cultural differences in fractions understanding exist.	The Korean language may make fractions more transparent (e.g., of four parts, one).
Children know and use various strategies to answer simple addition problems.	Children may answer the problem 3 + 4 by employing various strategies such as retrieval, counting on from the smallest or largest addend, counting their raised fingers, or decomposing the problem into a more manageable form. Children who have mathematical disabilities often make more mistakes than typically developing children when executing addition strategies.

Individual Differences in Intervention Effectiveness

In light of individual differences in students' prior knowledge and abilities, it is not surprising that the benefit of instructional interventions also varies for students with different backgrounds. In this section, three instances are described where the effectiveness of worked examples depends on characteristics of the student experiencing the intervention.

Perhaps the most intuitive of these findings is a case in which the effectiveness of the presented worked examples depended on the ability level of the learner. Grosse and Renkl (2007) presented college students, who possessed varying levels of prior knowledge about probability, with correct and incorrect worked examples. For correct examples, students explained what procedure was used and why it was correct; in incorrect examples, students located the error and fixed it. This combination led to improved learning for students with sufficient prior knowledge. However, students with low prior knowledge did not benefit from inclusion of incorrect examples. Further results from this study suggested that highlighting the portion of the problem containing the error increased the benefit for low-ability learners.

Another instance in which students' prior knowledge affects the degree to which they benefit from instruction shows the opposite effect. Kalyuga et al. (2001) demonstrated that inexperienced students benefited more from studying worked examples than did higher ability students. This type of finding is referred to as an 'expertise reversal effect,' in which interventions that provide instructional guidance are effective for low-knowledge learners who may not have internal schemas activated at the time, but are less effective or even harmful for more experienced learners who become overloaded by simultaneous activation of internal and external schemas (Kalyuga et al., 2003).

Finally, Booth et al. (under review) demonstrate that the benefit of worked examples may vary for students with different ethnic backgrounds, regardless of prior ability level. In their study, minority (Black/Latino) students benefited more than nonminority (White/Asian) students from explaining correct and incorrect examples while practicing solving equations. An achievement gap between minority and nonminority students existed at pretest, and was closed at posttest. However, both high- and low-ability minority students benefited more from the inclusion of worked examples than from problem-solving practice alone, suggesting that the differential benefit was not due to cognitive differences between the groups. In this particular case, incorrect examples were designed to facilitate correct encoding of problem features and to illustrate that errors are an important part of the learning process, perhaps decreasing stereotype threat and increasing minority students' self-efficacy for the task.

In summary, even for interventions that improve learning, individual differences in student characteristics impact their effectiveness. It is clearly important for researchers and practitioners to familiarize themselves with typical stumbling blocks inherent in mathematics learning and interventions that successfully overcome them. However, it is also crucial to be aware that individual differences in cognitive and motivational factors (e.g., self-efficacy) may influence the degree to which students will be able to benefit from the intervention and overcome their stumbling blocks (Table 9).

Table 9 Summary of individual differences in intervention effectiveness

Finding	*Example*
The effectiveness of instruction varies based on students' prior knowledge.	High-ability undergraduates learned more from finding and fixing algebraic mistakes; however, lower ability undergraduates learned more from studying worked examples.
The effectiveness of instruction varies based on students' motivation for learning.	Explaining correct and incorrect examples was more beneficial for students from underrepresented minority groups who held lower beliefs about their own self-efficacy.

Abstract

The theory of cognitive dissonance states that inconsistency between beliefs or behaviors creates an aversive motivational state akin to hunger or thirst. This tension is typically reduced by changing one of the dissonant elements, or adding new ones, until mental consonance is achieved. There have been three major revisions relevant to modern interpretation of dissonance phenomena. Aronson's self-consistency model (1968) proposed that dissonance resulted from behaviors that were discrepant with one's conception of oneself as a decent and sensible person. Steele's self-affirmation theory (1988) proposed that dissonance emerged from threats to the overarching self-system, and that dissonance reduction relied on reestablishing the integrity of the global self-concept. Cooper and Fazio's 'New Look' model (1984) proposed that dissonance resulted from creating unwanted aversive consequences and did not require cognitive inconsistency. A recent synthesis discussed by Cooper (1999) and Stone (1999) suggests that dissonance is caused by a discrepancy between the outcome of a behavioral act and the standard to which it is compared. According to this self-standards model, contextual variables determine the comparison standard, and it is this standard that determines which dissonance process is most likely to be operative.

Foundations of Dissonance Theory

The theory of cognitive dissonance is elegantly simple: it states that inconsistency between two cognitions creates an aversive state akin to hunger or thirst that gives rise to a motivation to reduce the inconsistency. According to Leon Festinger (1957), cognitions are elements of knowledge that people have about their behavior, their attitudes, and their environment. As such, a set of cognitions can be unrelated, consonant, or dissonant with each other. Two cognitions are said to be dissonant when one follows from the obverse of the other. The resultant motivation to reduce dissonance is directly proportional to the magnitude and importance of the discrepant cognitions, and inversely proportional to the magnitude and importance of the consistent cognitions. This tension is typically reduced by changing one of the cognitions, or adding new cognitions until mental 'consonance' is achieved. Festinger's original formulation proved to be one of the most robust, influential, and controversial theories in the history of social psychology. Although a number of challenges and revisions have been suggested, the basic behavioral observation remains uncontested and continues to stimulate fresh research.

Application of this theory has yielded many surprising and nonintuitive predictions. For example, conventional wisdom suggests that behavior follows from attitudes; dissonance theory, however, identifies conditions under which just the opposite occurs. An early and often replicated experiment illustrates the power and counterintuitiveness of the theory. In what is now known as the induced compliance effect, Festinger and Carlsmith (1959) asked individuals to perform 30 min of a mind-numbingly tedious activity, and then to persuade a waiting participant that the activity was in fact quite interesting. This situation created cognitive dissonance in most individuals – they believed that the task was boring, yet inexplicably found themselves arguing quite the opposite. Half of the participants were given a ready excuse for telling this lie – they were paid $20 to do so – while the other half, paid only $1, had no such excuse. Those with a clear justification for their odd behavior experienced no dissonance and, as one would expect, later reported that the task was rather boring. The other half, however, given insufficient justification for their behavior, experienced dissonance between the knowledge that the task was boring and the reality that they were misleading a fellow participant into believing the opposite. Rather than endure the aversive experience of believing one thing but saying another, these individuals changed their opinion and convinced themselves that the task was actually interesting. In other words, their attitude was shaped by their behavior.

Subsequent studies have confirmed the basic theory of cognitive dissonance and demonstrated its far-reaching impact. For example, cognitive dissonance explains the increased commitment so frequently observed following a severe initiation into a group. The theory also explains why, when faced with a choice among several desirable options, we observe the tendency to highlight positive aspects of the chosen option and negative aspects of the rejected alternatives after (and only after) the choice has been made. In the course of such studies, we have learned much about the boundary conditions associated with the theory and have identified anomalies not easily explained by the original theory. Since the 1960s, a number of theoretical revisions have sought to subsume these limitations under a unifying theory. This article summarizes briefly the leading reformulations of dissonance theory and speculates on future directions.

An Early Theoretical Challenge: Self-Perception Theory

Dissonance did not come quietly into psychology, nor did controversy begin over the finer points of the underlying process. Rather, the theory challenged the reigning theoretical paradigm of behaviorism of the 1950s by questioning the sovereign utility of basic learning theory. Rather than increased rewards leading to more positive attitudes, Festinger and Carlsmith (1959) had shown quite the opposite: participants who received a smaller reward for counterattitudinal advocacy

[†] Deceased

developed more positive attitudinal responses. The majority of early criticisms, therefore, focused not on the details of the dissonance theory but rather on its fundamental legitimacy. During parts of the next two decades, one of the enduring intellectual feuds in social psychology debated whether dissonance phenomena were the result of complex cognitive processes in the mind of the participant, or whether they were merely the result of complex cognitive processes in the mind of the experimenter. Daryl Bem (1972) took the position that one could derive similar predictions through far more parsimonious behavioral processes. He argued that participants in dissonance experiments were not experiencing negative psychological tension due to inconsistency, but rather were simply inferring their attitudes from their behavior and the situation in which it occurred. In essence, he suggested that people view their own behavior as though they were outside observers, and infer their underlying attitude from an analysis of their behavior. In support of this position, Bem replicated Festinger and Carlsmith (1959) and demonstrated that independent observers, aware of the monetary inducements, attributed attitudes to the participants that were nearly identical to the participants' actual attitudes. The critical test between these theories revolved around the search for physiological arousal. Festinger was quite clear that inconsistent cognitions created an aversive motivational state that could presumably be measured. Bem's self-perception theory, by contrast, predicted neither psychological nor physiological tension. However, Zanna and Cooper (1974) found indirect evidence for physiological arousal by showing that if arousal were misattributed to an irrelevant source, the effects of dissonance disappeared. The debate over dissonance versus self-perception was finally laid to rest by a series of experiments that identified the precise conditions under which each was operative. Fazio et al. (1977) found that small discrepancies between attitude and behavior (defined as those within a person's latitude of acceptance) tended to elicit self-perception processes, but larger discrepancies (those that fall in the person's latitude of rejection) were more likely to generate dissonance processes. Croyle and Cooper (1983) added direct support for Festinger's original position by showing that engaging in counter-attitudinal advocacy, at least outside people's latitude of acceptance, is marked by measurable increases in people's skin conductance responses. Ultimately, the importance of self-perception theory lay in its contributions to identifying boundary conditions of dissonance processes and in provoking research that established physiological arousal as one of the hallmarks of dissonance.

Introduction of the Self

It may be that all cognitive inconsistencies are not psychologically equivalent. According to some theorists, inconsistencies that implicate aspects of the self-maintain a privileged position. This suspicion led Elliot Aronson (1968) and Claude Steele (1988) to consider the role of self-concept in the dissonance process. Aronson concurred with Festinger's view that dissonance was caused by inconsistencies, but argued that it was a particular inconsistency that mattered most in arousing dissonance, i.e., the discrepancy between a person's general expectations for the self and his or her actual behavior. In other words, the arousal due to dissonance came about when a person's belief that he or she was a good and rational individual was called into question by behavior that was neither good nor rational. Aronson predicted that dissonance arousal would be more frequent and more powerful among those with high self-esteem – that is, among those whose past history had led them to believe that their high internal standards of behavior were likely to be achieved. By contrast, Aronson predicted that those with low self-esteem, who were accustomed to behaving less competently, would not be surprised or discomfited to find themselves once again behaving in an incompetent manner.

To illustrate his point, Aronson (1968) argued that the dissonance aroused in Festinger and Carlsmith's (1959) experiment was not due to inconsistency between the thoughts "I believe the task was dull" and "I told someone the task was interesting." Instead, Aronson proposed that dissonance was aroused by inconsistency between cognitions about the self (e.g., "I am a decent and truthful human being") and cognitions about the behavior (e.g., "I have misled a person … (and) conned him into believing something that just isn't true," p. 24). Aronson concluded: "at the very heart of dissonance theory, where it makes its clearest and neatest prediction, we are not dealing with just any two cognitions; rather we are usually dealing with the self-concept and cognitions about some behavior. If dissonance exists it is because the individual's behavior is inconsistent with his self-concept" (1968, p. 23).

Claude Steele (1988) suggested a different interpretation of the role of the self in creating dissonance. Like Aronson, Steele viewed inconsistent cognitions as a threat to the self; but unlike Aronson's self-consistency model, he suggested that the primary function of dissonance reduction was not to rescue the specific self-cognitions threatened by a behavioral outcome, but instead to restore the completeness of the overarching self-system. The difference, then, was not about the origin of dissonance arousal, but rather about the purpose and mechanism underlying dissonance reduction. Whereas Aronson focused on individual susceptibility to dissonance arousal, Steele's self-affirmation theory focused on individual resilience to dissonance. Interestingly, from Aronson's point of view, it is those individuals who have a positive self-regard that are most likely to experience dissonance arousal. Steele, by contrast, asserted that it is those same individuals – wrapped in their armor of self-resources – who feel immune from the need to reduce dissonance. Based on the data provided by Aronson and Steele, it is probably fair to say that those with high self-esteem are both more susceptible to dissonance arousal and more resistant to its effects because they can focus on their many other strengths. Holding all else constant, high self-esteem serves both as a catalyst that generates dissonance and as a buffer that mitigates the need to reduce dissonance.

A New Look at Dissonance

In 1984, Cooper and Fazio provided a comprehensive review of the dissonance literature and challenged the dominant assumption that dissonance was driven by a need for psychological consistency. According to their 'New Look' model, dissonance is aroused when people perceive that their behavior has been responsible for bringing about consequences that are

unwanted or aversive. If there are no such consequences, then inconsistent behavior will not produce the state of dissonance. For example, Cooper and Worchel (1970) replicated Festinger and Carlsmith's (1959) study with a condition in which the waiting participant was not convinced by the subject's lie. In this condition, the aversive consequence of misleading a fellow participant was removed along with all evidence of the dissonance process. Cooper and Fazio concluded from this and many other studies that responsibility for an aversive event rather than cognitive inconsistency plays the vital role in producing cognitive dissonance.

Future Directions – Self-Standards Model of Dissonance

Each of these reformulations of dissonance theory differs with respect to one major issue: what is the role of self-concept in dissonance processes? Is it a problem, a benefit, or completely irrelevant to the arousal and reduction of cognitive dissonance? There are data in favor of each position – data that are not easily reconcilable. However, a recent synthesis discussed by Cooper (1999) and Stone (1999) suggests that dissonance is caused by a discrepancy between the outcome of a behavioral act and the standard to which it is compared. According to the self-standards model, sometimes the standard that people use to measure their behavioral outcomes are personal and idiosyncratic. In such cases, people's views of themselves will play a crucial role. At other times, the assessment of an act is based on broad, normative standards that are shared in the culture. At these times, the self will not play a role in the dissonance process.

In summary, it is still useful to think of dissonance as involving inconsistency among cognitive elements and to conclude that inconsistency produces motivation for change. It is also fair to conclude that the future of dissonance theory will include a role for behavioral consequences, an assessment of the self, and an analysis of the contextual variables that make different standards the basis of judgment for behavioral outcomes. The evolution of cognitive dissonance calls for an integration that will likely include insights from the currently dominant perspectives.

Editor's Note

This article appeared in the first edition of the Elsevier *Encyclopedia of Social and Behavioural Sciences* (2001). Since then cognitive dissonance continues to interest social psychologists and to feed research on different fields such as health attitudes (smoking, eating habits), political attitudes (voting behavior, opinion polls, and election campaigns), and marketing. Dissonance theory also fed theories about system justification (see also Kay et al., 2002; Jost et al., 2003). Moreover, developments on attitudes theory showed that explicit but not implicit attitudes are affected by dissonance (Gawronski and Strack, 2004). There are still debates around the theory that can be traced in Brehm's (2007) review and a more recent Kenworthy et al. (2011) trans-paradigm theoretical synthesis of cognitive dissonance theory. In this article the authors using modern statistical techniques aim to test five research paradigms. The recent interest in and the development of neuroscience techniques showed brain activity at the moment of the decision phase in a decision-based cognitive dissonance paradigm (Jarcho et al., 2011) and suggest that the mere act of making a choice can change self-report preference and its neural representation (Izuma et al., 2010). It seems that cognitive dissonance is a theoretical field that will continue to trigger basic and applied research.

Cognitive Maps

Rob Kitchin, National University of Ireland Maynooth, Maynooth, Ireland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A cognitive map is a representative expression of an individual's cognitive map knowledge, where cognitive map knowledge is an individual's knowledge about the spatial and environmental relations of geographic space. For example, a sketch map drawn to show the route between two locations is a cognitive map – a representative expression of the drawer's knowledge of the route between the two locations. This map can be analyzed using classification schemes or quantitatively using spatial statistics. The drawing of a cognitive map is supplemented by a range of other techniques designed to measure various aspects of cognitive map knowledge, including distance and direction tasks and more recently brain scans. These measures are important because they reveal fundamental aspects of cognition and the cognitive processes that underlie spatial decision and choice making.

Introduction

A cognitive map is a representative expression of an individual's cognitive map knowledge, where cognitive map knowledge is an individual's knowledge about the spatial and environmental relations of geographic space. For example, a sketch map drawn to show the route between two locations is a representative expression of the drawer's cognitive map knowledge. While the term cognitive map suggests a representation that corresponds cartographically to how geographic knowledge is held within the mind, the term is used more metaphorically to capture the notion that people and animals possess such knowledge and use it to navigate and make spatial decisions and choices that affect spatial behavior – why we choose certain routes, places to visit, locations to live, and so on. Indeed, there is much debate as to the extent to which cognitive map knowledge consists of imagery and representations or other forms of knowledge, encodes spatial relations (such as distance, scale and direction), links spatial and nonspatial information, how it is mentally organized and stored, and is shaped by cognitive, neurological, and external factors (see Kitchin and Blades, 2002). Because cognitive map knowledge represents and demonstrates an individual's geographic knowledge, geographers, psychologists, and others seek to capture such information through various tests in order to assess how we learn, process, and store geographic information gained from primary (e.g., walking through an area) and secondary (e.g., reading a map) sources.

Cognitive Mapping

The combined processes by which we learn, store, and use information relating to the geographic world are known as cognitive mapping. Cognitive mapping as a field of enquiry is relatively young. While a handful of studies predate 1960, the majority of research has occurred since the publication of Kevin Lynch's seminal work *The Image of the City* (Lynch, 1960). This book examined how people understood and remembered the geography of US cities. The cognitive mapping research that followed has been a multidisciplinary endeavor, undertaken by geographers, psychologists, anthropologists, computer and information scientists, and neurologists. By examining how different populations (e.g., varying ages of children, people without sight, or the two sexes) learn and employ geographic knowledge, research has sought to understand how people and animals acquire cognitive mapping abilities across the lifespan and to document and understand fundamental processes of spatial and environmental cognition. Despite the vast amount of research that has been conducted, as yet there is only limited consensus as to the nature of cognitive mapping. As such, there are a number of theories that seek to explain how we construct, process, and store cognitive map knowledge and how this knowledge is used to make spatial decisions and choices.

Until recently, most of these theories have been grounded in cognitive and environmental psychology and concern fundamental processes of spatial cognition and how people and animals come to spatially understand the world (Golledge and Stimson, 1997; Kitchin and Blades, 2002). In such cases, an interactionalist perspective has largely been adopted wherein there is a Cartesian separation of mind from the external world, of individual from environment, with the elements of the latter understood as inputs and the source of causal effects on spatial knowledge and cognition. More recently, such theories have been challenged from two predominant sources. One set of studies have focused not on psychological processes but on neurological processing and how the brain functions to enact spatial cognition and behavior (Byrne et al., 2007). The second set of studies are transactional in nature, in that they do not separate individuals from environment, but rather see sociocultural context as constitutive of spatial cognition; spatial choices and decisions are not simply the result of disembodied spatial reasoning but are grounded in the unfolding transaction between individual and the world (Heft, 2013). All of these theories are underpinned by studies that seek to capture cognitive map knowledge (see Downs and Stea, 1977; Gärling and Golledge, 1993; Portugali, 1996; Golledge and Stimson, 1997; Kitchin and Blades, 2002; Montello, 2009).

Cognitive Maps

Traditionally, the bases and processes of human cognitive mapping was exclusively measured and assessed through

sketch maps and other external forms of knowledge representation (e.g., estimating distances). More recently, these methods of data generation have been supplemented by qualitative and neurological approaches. Moreover, there has been a transference of experimental setting from the laboratory to natural and virtual environments.

Sketch Maps

Sketch maps have long been used as a method to capture cognitive map knowledge, consisting of a drawing of how an individual understands the spatial relations of an area. In experimental conditions, subjects are given a sheet of paper and are asked to draw a map of a certain location, area, or route between locations (alternatively, they might be asked to make a map using some building blocks). The scale of the geographic realm to be drawn can vary substantially from the global (e.g., draw a map of the world) to the local (e.g., draw a map of your street or neighborhood) (Appleyard, 1970). Variants on this simple sketch mapping exercise include providing respondents with a small portion of the map to provide a scale and reference (e.g., Pearce, 1981) and teaching subjects a sketch map language where specific symbols are used to denote particular features (Beck and Wood, 1976). By aggregating together the cognitive maps of several individuals, it is possible to determine their shared level of knowledge and which elements of an environment are most salient. This is the technique pioneered by Lynch (1960). He analyzed individuals' maps by classifying their elements into five different classes (see **Table 1**) which he then used to produce a composite map where the symbol size/shading density is proportional to the number of times an element appeared on the individual maps. Using this technique, he aggregated together the sketch maps of residents in Boston, Jersey City, and Los Angeles to create composite cognitive maps of these cities (see **Figure 1**).

The analysis used by Lynch is a content classification. A number of other classification schemes have been used to analyze sketch maps. For example, there have been classifications that assess map style, structure, and accuracy. In these cases, the focus moves beyond what elements an individual draws to assessing the relationship between the elements and their relativity to the real world. In addition, the accuracy of the spatial relations portrayed can be analyzed statistically using spatial statistics. For example, in many studies bidimensional regression has been used to compare the geometry of the cognitive map to a cartographic map (Golledge and Spector, 1978; Waterman and Gordon, 1984). Bidimensional regression is a two-dimensional equivalent of linear regression that quantifiably assesses scale, rotation, and translation differences between an actual and an estimated pattern of responses.

Using the technique of sketch mapping to generate data about a person's cognitive map knowledge and their ability to use this knowledge is not without criticism. For example, a number of researchers have argued that sketch maps have a number of qualities that make them unreliable and inaccurate measures of spatial knowledge (note not geographic knowledge): they are dependent upon drawing ability and familiarity with cartographic conventions; they suffer from associational dependence where later additions to the sketch will be influenced by the first few elements that are drawn; their content and style are influenced by the size of paper used for sketching; they are difficult to subjectively score and code; and they often show less information than the respondent knows (Beck and Wood, 1976; Blades, 1990; Hart, 1981). As a consequence of these criticisms, it is becoming less common for researchers to use sketch mapping as an analytical tool to assess individual and collective cognitive mapping. Instead, researchers are turning to a range of other techniques.

Table 1 Lynch's classification

Category	*Description*
Paths	Paths are the channels along which an individual moves. They may include streets, walkways, and railways
Edges	Edges are the linear elements not considered as paths. They are the boundaries between two phases, linear breaks in continuity such as shores or walls
Districts	Districts are the medium-to-large scale sections to the city, conceived as having a two-dimensional extent, which the observer mentally enters, and which have some common identifiable character
Nodes	Nodes are points, the strategic spots in the city into which an observer can enter, and which are the intensive foci to and from which (s)he is traveling. They may be primarily junctions, transportation changeovers, a crossing, or convergence of paths
Landmarks	Landmarks are another type of point reference. They are usually a physical object such as a building, sign, store, or mountain

Other Action Measures

Other forms of action (e.g., drawing) measures can be divided into those that, like sketch mapping, are two-dimensional in nature and those that are unidimensional. Other two-dimensional measures include completion tasks and recognition tasks. Completion tasks require an individual to complete a task that has already been started for them. For example, spatial cued response tests require subjects to place locations in relation to locations that are preplaced (Thorndyke and Hayes-Roth, 1982). A highly cued version of this are cloze procedure tests that require a subject to 'fill in' a missing space (an aspatial example of which would be, 'a dog barks but a cat ------?') (Robinson, 1974). Recognition tasks measure subjects' success at identifying spatial relationships. Iconic tests require the respondent to identify correctly features on a map or aerial photograph (Matthews, 1984). Configuration tests require a subject to identify correctly which configuration, out of several, displays the correct spatial relations (Evans et al., 1984). Verifiable statement tests require subjects to identify whether a textual description of a spatial relationship is true or false (Ferguson and Hegarty, 1994). Spatial cued response data are often analyzed like sketch maps using bidimensional regression. Cloze procedure and recognition tests are analyzed by constructing an accuracy score that reveals as a percentage the number of correct placements or recognitions (Kitchin and Blades, 2002).

Figure 1 Cognitive maps of Boston, Jersey City, and Los Angeles.

Unidimensional tests seek to uncover one-dimensional aspects of cognitive map knowledge such as distance and direction. These dimensions are thought to be representative of spatial knowledge in general but are particularly useful for measuring levels of route (procedural) knowledge. Distance tasks are used to assess an individual's knowledge of the distance between locations. In his review, Montello (1991) identifies five groups of tests designed to measure cognitive distance estimates: ratio scaling, interval and ordinal scaling, mapping, reproduction, and route choice. Ratio scaling adapts traditional psychophysical scaling techniques to a distance context, with subjects estimating the distance to

a location as a ratio of some other known distance, such as an arbitrary scale or the length of a ruler. Interval and ordinal scaling are similar to ratio scaling but differ in their level of measurement: paired comparison requires a respondent to decide which one of a pair of distances is longer; ranking requires a respondent to rank various distances in order along the dimension of length; rating requires a respondent to assign the distance between places to a set of predetermined classes that represent relative length; partition scales require a respondent to assign distances to classes of equal-appearing intervals of length. Mapping is the measurement of distances from a sketch map for comparison with the actual distances (Montello, 1991). Reproduction requires a respondent to provide distance estimates at the scale of the estimated distance (Herman and Klein, 1985). Route choice consists of inferring judgments of cognitive distance from the choice of route an individual makes when asked to take the shortest route between two locations.

Like sketch map data, distance data can be analyzed individually or aggregated to provide data about a group. A common method to analyze ratio scaling, mapping, and reproduction data is to regress the cognitive distance estimates onto the objective distance values, observing the relationship between the two (Cadwallader, 1973). Another common strategy, and one also used with interval or ordinal distance data, is to analyze the data using multidimensional scaling techniques (MDS) (Harman and Betak, 1976). MDS techniques explore the latent structure of a set of distance estimates by assessing the dimensionality of the data. They do this by constructing a two-dimensional space from one-dimensional data using a series of algorithms. In essence, they construct a 'map' showing the relationships among a number of objects. This 'map' can then be compared to an actual map using techniques such as bidimensional regression (Kitchin, 1996).

Direction tasks assess an individual's knowledge of the direction between two locations. The most common direction task is pointing. Pointing involves standing at, or imagining being at, a location and pointing to another location (Kirasic et al., 1984). An alternative technique involves drawing on a compass the direction to a location from another (Tversky, 1981). Direction estimates have been analyzed by comparing the estimates to the actual directions, often through a simple subtraction process. In other cases, a technique of projective convergence has been used to construct a 'map' from estimates by calculating where estimates to the same location but from different sites intersect (Kitchin, 1996).

Qualitative Approaches

In recent years, there has been an increase in the use of qualitative methodologies to investigate cognitive map knowledge. In some cases, this has involved a scientific approach and in others an interpretative approach. The scientific approach continues the tradition described earlier, but rather than externally representing their knowledge through actions (e.g., drawing, pointing) individuals are required to describe verbally routes or layouts in experimental conditions (Taylor and Tversky, 1992). Like sketch maps these data can be analyzed for content, style, structure, and accuracy. The interpretative approach, however, is less structured in terms of data collection. It posits that talking to and observing individuals as they interact with an environment reveals information concerning spatial behavior. Such an approach might seek to gain a spatial understanding of an area by adopting a strategy of in-depth interviews, discussing the reasoning behind spatial decision making (Kitchin, 1997).

Neurological Approaches

In contrast to the earlier approaches, which seek to understand the process of cognitive mapping by examining external measures (action or verbal), neurological approaches measure neural activity within the brain (Dudchenko, 2010). A set of brain-scan techniques exist, differentiated by their temporal and spatial resolution. Magnetic electroencephalography has a high temporal resolution (0–300 ms) but low spatial resolution (providing only a general indication of neural activity). Positron emission tomography is the converse, with functional magnetic resonance imagery (fMRI) providing a middle ground for both parameters. To reveal information about spatial cognition, scans are taken as the individual undertakes a series of spatial, problem-solving tasks. As such, neurological approaches seek to explain spatial thought and spatial behavior by identifying its neural, physiological bases rather than its psychological basis. To date few studies have sought to marry the findings of neurological and psychological research to provide a comprehensive, physiological, and psychological model of cognitive mapping.

Naturalistic Settings

Many studies, particularly from psychology, which seek to understand cognitive map knowledge are conducted in controlled laboratory settings. For example, respondents may be required to learn the layout of objects in an experimental laboratory and then to map the location of objects or estimate distance and directions between objects. The laboratory is attractive to researchers because they can control/monitor all the variables that may affect spatial learning and processing and thus isolate those that are particularly salient. Some researchers, however, question the ecological validity of this approach given that cognitive map knowledge concerns the geographic environment and it is this environment in which spatial behavior occurs (Golledge and Stimson, 1997; Kitchin and Blades, 2002). The real world is inherently messy and full of factors that cannot easily be controlled and that work in concert with each other. Data collected in a laboratory then do not mirror real life, and salient variables do not work in isolation. For these reasons, they suggest that testing should occur in the natural environment, and increasingly this is becoming more common (Gale et al., 1990; Jacobson et al., 1998).

Virtual Environments

The development of sophisticated virtual, immersive 'game spaces' has provided a new means to assess cognitive mapping. Such virtual environment are attractive to researchers because they can appear highly naturalistic through the use of photo-realistic graphics but are nevertheless highly controlled

environments; the researcher can limit and isolate inputs and contextual factors, and virtual environments are entirely measurable in precise ways with regards to location and individual reactions (Peruch et al., 2000). Such systems can also measure physiological factors such as eye and body movement. For these reasons, studies using virtual environments have become quite common in the past decade (e.g., Mou et al., 2013). It is likely that these studies will be supplemented by those utilizing the recent development of augmented reality – virtual displays overlaid on natural environments – as a measurement technique, an approach that allows the blending of naturalistic and virtual terrains.

Summary

Cognitive map knowledge concerns how we learn, store, and process knowledge of the geographic environment. A variety of theories designed to explain such cognitive mapping have been tested using a variety of measures, applied across different groups and settings. The outputs of these measures are, in essence, cognitive maps – externalized representations of cognitive map knowledge. Such representations are important because they reveal fundamental aspects of cognition and the cognitive processes that underlie spatial decision and choice making.

Cognitive Modeling: Connectionist Approaches

Bruce MacLennan, University of Tennessee, Knoxville, TN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Connectionist approaches to cognitive modeling make use of large networks of simple computational units, which communicate by means of simple quantitative signals. Higher-level information processing emerges from the massively parallel interaction of these units by means of their connections, and a network may adapt its behavior by means of local changes in the strength of the connections. Connectionist approaches are related to neural networks and provide a distinct alternative to cognitive models inspired by the digital computer.

Definitions

To facilitate the following discussion, it will be helpful to define some terms. A typical connectionist network comprises a (potentially large) number of simple processing 'units.' The units are often called (artificial) neurons, but that terminology begs the question of their relation to biological neurons, so it will be avoided here. In the most common case, the units form a weighted sum of their (quantitative) inputs and pass the result through a simple, nonlinear 'activation function,' which limits the range of possible outputs. The resulting value is considered the 'activity' of the unit, which may be transmitted to other units (through outgoing connections). In some cases the activity of a unit is a combination of its inputs and previous activity, which provides a kind of short-term memory residing in the collective activities of the units.

The weighted sum results from the fact that each connection in the network has an associated 'weight' (analogous to synaptic efficacy in biological neural networks), which multiplies the quantity transmitted by that connection. Positive weights correspond to excitatory connections and negative weights to inhibitory; zero-valued weights correspond to the absence of a connection. Mathematically, connection weights are often treated as a 'weight matrix' $\mathbf{W}$, with element W_{ij} being the weight of the connection to unit i from unit j. Learning and adaptation take place by modification of the weights according to some 'learning algorithm' (described later); thus the connections constitute the network's long-term memory. 'Connectionism' derives its name from the fact that knowledge resides in the patterns and weights of the connections.

Many connectionist networks are organized into 'layers,' analogous to functional areas in the brain; information usually moves in lockstep from layer to layer. Although many networks are 'feed-forward,' that is, the information moves through successive layers from input to output, other networks are 'recurrent,' which means that there may be feedback connections from a layer to itself or to earlier layers. Recurrent networks are able to recognize and process 'temporally extended patterns,' that is, sequences of related inputs.

It must be stressed that there are exceptions to all of the preceding general statements about connectionist networks, and connectionist approaches are best viewed as forming a Wittgensteinian family resemblance.

History

A short history of connectionist approaches will be presented, first in the narrower context of cognitive science and artificial intelligence (AI), and then in the broader context of epistemology, linguistics, and the philosophy of mind. Although the size of this article does not permit detailed citations of the literature, many of the seminal articles are collected in Anderson and Rosenfeld (1988) and Anderson et al. (1990). *See* Cognitive Psychology: History.

Narrower History

According to the second edition of the *Oxford English Dictionary*, the term 'connectionism' was first used by E. L. Thorndike in his *Fundamentals of Learning* (1932) to refer to the reduction of mental processes to the connections between stimuli and responses, that is, to a form of associationism, and so connectionist theories have been set in opposition to cognitive theories. The term is used somewhat differently now (so that 'connectionist cognitive science' is not an oxymoron), but retains some similarities to associationism. However, to understand the relation it is better to look at connectionism from the perspective of neural network models of cognition.

In the early 1940s, W. S. McCulloch and W. Pitts investigated the computation of logical functions by simple neuron-like elements; in effect they showed that these elements could compute logical 'and,' 'or,' 'not,' and so forth. In his *Organization of Behavior*, D. O. Hebb (1949) suggested that learning takes place by the formation of 'cell assemblies,' and that this occurs through the strengthening of connections between simultaneously active neurons in neural networks, which are initially randomly connected. His description of this process inspired one of the simplest connectionist learning rules (described later).

In the late 1950s, F. Rosenblatt began to investigate the application of simple neuron models called 'perceptrons' to perceptual problems such as classifying printed letters. He developed a learning algorithm for simple (single-layer) perceptron networks, which iteratively adjusted the connection weights (strengths) whenever the network made a mistake. He proved that if the network were capable of solving the problem at all, then the algorithm would eventually find the connection weights to solve it. However, there are many problems that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43021-7

a single-layer network cannot solve, and Rosenblatt never succeeded in finding a multilayer learning algorithm.

A key event in the history of connectionism was the publication of M. Minsky and S. Papert's *Perceptrons* (1969), which demonstrated limitations of simple perceptron networks. Specifically, they proved that single-layer perceptron nets could discriminate only those categories that are 'linearly separable'. Their proof did not apply to multilayer nets (for which there was still no learning algorithm), but they suggested that similar limitations would be found for these too. Nevertheless, their book was widely interpreted as showing the impotence of neural networks in general, and is commonly blamed for discouraging research in the field for a decade. (The extent to which it actually did so is perhaps a topic for historians of science.)

It will be worthwhile to comment on the role of holography in the development of connectionist approaches. As early as 1929, K. S. Lashley had conducted experiments suggesting that individual memory traces were not localized in any one place, and that degradation of memory was proportional to the amount of cortical mass destroyed, thus implying that individual traces were distributed over large areas of cortex. In a well-known 1950 paper, he despaired of ever understanding how such a nonlocal memory could operate (Lashley, 1950). The principles of holography had been described by D. Gabor in 1949, but it was not until the advent of optical holography in the early 1960s that it began to be seen as a solution to Lashley's dilemma. Although an analogy between holography and memory had been suggested as early as 1963 by P. J. van Heerden, the holographic hypothesis has been developed most extensively by K. H. Pribram and his colleagues since 1966 (see, e.g., Anderson et al., 1990, Chapter 7). In the late 1960s and early 1970s, holographic and holography-inspired models of associative memory were also investigated by H. C. Longuet-Higgins, D. J. Willshaw, and others (Hinton and Anderson, 1989). Some connectionists were influenced by the critiques of traditional, rule-based AI by the phenomenologist philosopher H. L. Dreyfus (*What Computers Can't Do*, 1972). Although he stressed the limitations of rule-based systems, he also explained that some of these limitations would not apply to analog systems operating on principles similar to holography. *See* Distributed Cognition; Memory Trace, Nature of; Models of Neural Basis of Learning and Memory.

Although a number of investigators (including J. A. Anderson, S. Grossberg, and T. Kohonen) continued connectionist research through the 1970s, the field was quiet until rejuvenated by the work of D. E. Rumelhart, J. L. McClelland, and other members of the PDP (Parallel Distributed Processing) Working Group. Many of their publications were collected in a widely read two-volume set (Rumelhart et al., 1986). The credibility of connectionist approaches was also enhanced by J. Hopfield's publication in 1982 of a simple recurrent net capable of associative memory and pattern completion.

Broader History

Although connectionism can be viewed as an approach to knowledge representation and inference of relevance only to cognitive science, in fact it has much broader implications, for it challenges assumptions about knowledge that have been largely unquestioned since ancient Greek philosophy. Already in the philosophies of Socrates, Plato, and Aristotle, there is a preference for knowledge expressed as logical relations among discrete, language-like structures, and for a view of cognition as mechanized deduction. These ideas influenced many later philosophers, including Hobbes (who equated thinking with computation), Leibniz (who experimented with formalized systems of knowledge representation and mechanical deduction), and Boole (who invented mathematical logic). These ideas were also influential in the development of logical positivism, which dominated the philosophy of science in the first half of the twentieth century. The idea persisted in the assumption that there must be a 'language of thought,' because it is 'the only game in town' (i.e., no one could think of an alternative). Similarly, most research in AI took for granted that intelligence resides in the structures of a 'knowledge representation language' and in deduction-like formal rules for their manipulation. Throughout the 1970s, AI researchers concentrated their attention on expert systems, which depended on expertise represented symbolically. Disappointment with the performance of these systems was one of motivations for the connectionist renaissance.

In summary, the Western tradition (with some exceptions) has displayed a kind of linguistic chauvinism, which presumes that all knowledge and cognition can be expressed in language-like structures. Knowledge is expressed at a 'symbolic' level, that is, in terms of atomic (indivisible), word-level categories related by sentence-like logical structures. On the other hand, most connectionist approaches represent knowledge at a 'subsymbolic' level, that is, in terms of minute, quantitative features related by low-level, often statistical, connections. In other words, knowledge is more akin to an image than to a sentence (*see* Mental Imagery: Visual Cognition). Therefore, some of connectionism's advocates see it as a fundamentally new view of knowledge and cognition, which is leading to a paradigm shift in cognitive science and philosophy and is engendering a new AI. Specific innovations of the connectionist approach are discussed below. *See* Artificial Intelligence: Connectionist and Symbolic Approaches; Knowledge Representations, Theory of.

Mechanisms of Adaptation and Learning

Virtually all connectionist approaches incorporate adaptive mechanisms or 'learning algorithms,' which allow the network to improve its performance; here a few will be discussed briefly.

Correlational Learning

'Correlational learning' ('Hebb's rule'), the simplest connectionist learning algorithm, takes its inspiration from Hebb's hypothesis that the simultaneous activity of two neurons strengthens the connection between them. It makes a change in connection weight proportional to the product of activities of the units it connects. Thus, the change in the weight W_{ij} of the connection to unit i from unit j is proportional to $\gamma_i x_j$, where γ_i

is the activity of unit i and x_j is the activity of j. This learning rule can be viewed as a highly simplified model of long-term potentiation. *See* Long-term Potentiation and Depression (Cortex); Models of Neural Basis of Learning and Memory; Regulation of Synaptic Efficacy.

The effect of this rule is that the weight becomes a correlation coefficient between the activities of the units it connects. That is, the connection will become stronger (more positive) to the extent that the units are simultaneously positive or simultaneously negative. The connection will become more inhibitory (more negative) to the extent that one unit is positive while the other is negative. If there is, on average, no systematic relation between the activities of the two units, then the weight will tend toward zero, effectively disconnecting the units.

The correlational learning rule is the basis of a simple associative memory known as a 'linear associator.' In this connectionist network, there are two layers of linear units, an input layer and an output layer; each input unit is connected to every output unit, so that the output is a linear function of the input, $\mathbf{y} = \mathbf{M}\mathbf{x}$. A series of pairs of pattern vectors $(\mathbf{y}_1, \mathbf{x}_1),\ldots,(\mathbf{y}_p, \mathbf{x}_p)$ may be presented to the input and output layers of such a network and the weights adjusted according to the learning rule. The goal of the linear associator is that the network associate each $\mathbf{x}_k$ with the corresponding $\mathbf{y}_k$. In fact, it can be shown that if the set of input patterns is orthogonal, then the output $\mathbf{W}\mathbf{x}_k$ will be proportional to the desired $\mathbf{y}_k$.

Delta Rule

An improvement called the 'delta rule' can be made in the linear associator; it illustrates a fundamental approach to connectionist learning. The idea is that we define the error, as a function of the weight matrix, as the sum of the differences between the desired and actual outputs of the network, $E(\mathbf{W}) = \sum_{k=1}^{p} D(\mathbf{y}_k, \mathbf{W}\mathbf{x}_k)$. The weight matrix is then changed by 'gradient descent,' which means that the elements of $\mathbf{W}$ are changed in the relative proportion that causes a maximal incremental decrease of $E(\mathbf{W})$.

If the difference between patterns is measured by Euclidean distance squared, $D(\mathbf{y}, \mathbf{y}') = \|\mathbf{y} - \mathbf{y}'\|^2$ (i.e., the sum-of-squares error), then the delta rule is essentially equivalent to linear regression. If the input patterns are linearly independent, then the delta rule will converge to a weight matrix that associates perfectly, $\mathbf{y}_k = \mathbf{W}\mathbf{x}_k$. If they are not, then the weight matrix will be that which minimizes the total error; that is, it will be the best linear prediction of the output patterns from the input patterns.

The delta rule also illustrates an important characteristic of most connectionist networks: their ability to generalize to inputs other than those upon which they have been trained. The delta rule provides only linear generalization, but other algorithms, such as backpropagation (see the next section), can make nonlinear generalizations. Typically, connectionist categories are represented by concrete prototypes rather than by definitions in terms of necessary and sufficient conditions or other abstract symbolic structures. Network behavior then depends on similarity to the prototypes rather than on formal manipulation of symbolic structures.

Backpropagation

Gradient descent may be applied also to multilayer networks of nonlinear units, so long as the activation function is differentiable. The 'backpropagation algorithm' (also called the 'generalized delta rule') efficiently computes the weight changes by starting with the last layer and working backward layer by layer. It has been rediscovered a number of times, perhaps first by P. Werbos in 1974, but its importance in connectionism began with its rediscovery in the early 1980s. There are also special adaptations of backpropagation for recurrent networks. Backpropagation has a number of limitations, including: (1) it may be quite slow, (2) it does not necessarily take the shortest path to an error minimum, and (3) it may get trapped in local minima. Nevertheless, it remains a fundamental learning algorithm and has been subject to many practical improvements. *See* Backpropagation.

Other Learning Algorithms

The preceding are examples of 'supervised learning' procedures, which means that the correct answer $\mathbf{y}_k$ is available for each training input $\mathbf{x}_k$. Although this is appropriate for modeling some cognitive processes and for many practical problems, for others 'unsupervised learning' is preferable. In these procedures, the network is not trained to produce any specific outputs, but it allowed to group or categorize inputs according to standards inherent in its design. Thus unsupervised learning is often equivalent to some kind of statistical clustering. Between these two extremes lies 'reinforcement learning,' in which the algorithm is told whether or not the output is correct, but not what the correct output is. In unsupervised and reinforcement learning, as in supervised learning, the network is normally expected to generalize to novel inputs reasonably. There are now hundreds of connectionist learning algorithms, of greater and lesser relevance to cognitive science and neuroscience, but this must suffice for an introduction. *See* Artificial Neural Networks: Associative and Self-organizing.

Example: Learning Past Tenses

Since the early 1980s, connectionist networks have been used for an enormous number of practical applications and for modeling many aspects of cognition. One notable example must suffice here; see Rumelhart et al. (1986) for additional examples.

Rumelhart et al. (1986, vol. 2, Chapter 18) trained a connectionist network to produce the past tenses of English verbs. The inputs were vectors representing phonological features of the present tenses and the outputs were vectors representing the phonological features of the corresponding past tenses. Learning was observed to pass through three stages. In the first stage, the most common verbs were learned, essentially by rote as individual special cases. In the second stage, the network learned how to form regular past tenses (for it was able to generalize to novel regular verbs), but overgeneralized by treating the (previously correctly processed) irregular verbs as though they were regular. In the

third stage, the network (re) learned the correct formation of the irregular past tenses without losing its ability to form regular past tenses. It is interesting and highly suggestive that children pass through these same three stages; the model also exhibited errors of the same kinds made by children.

Although this experiment can be (and has been) criticized on a number of grounds as a model of language learning, it is perhaps more valuable as a demonstration of how a connectionist network can exhibit apparently rule-like behavior, but not be following any explicit rules. In particular, exceptions to the rules are handled automatically without explicit accommodation. Thus it is paradigmatic of connectionist cognitive models.

Issues

Connectionist Representations

Connectionist approaches represent and process information in a way that is fundamentally different from symbolic approaches, in which knowledge is represented in discrete structures relating atomic lexical-level 'features' (i.e., categories of the sort for which natural languages have words). In symbolic approaches, information is processed by formal logic-like rules, which rearrange these atomic units of meaning. In connectionist approaches, on the other hand, information is represented by patterns of activity distributed over large numbers of units, which individually have no lexical-level meaning. The latter are often termed 'microfeatures,' but they are fundamentally different from features, which are supposed to be complete, context-free units of meaning. Microfeatures are just components of distributed representations and are usually individually uninterpretable.

Instead of rules, connectionist information processing is defined by quantitative connections between microfeatures and takes place at a subsymbolic level (Smolensky, 1988). Cognition then is an emergent effect of large numbers of these interactions (which therefore constitute the 'microstructure' of cognition). Indeed, according to this account, apparent symbolic processing is just such an emergent effect of these subsymbolic interactions.

Traditional (symbolic) models of knowledge have been criticized for their 'brittleness.' That is, when a set of rules is formulated in an attempt to model the behavior of some expert, it is generally found that the rules do worse than the expert, since the expert applies rules flexibly and makes ad hoc exceptions to them as required by the particulars of the situation. Of course, additional rules can be formulated to cover the exceptions, but then these are likewise found to have exceptions, and so forth. The attempt to reduce flexible behavior to inflexible rules leads to a combinatorial explosion of possibilities, which exceeds the capacities of brains and computers.

Connectionist approaches seem better able to account for the flexibility and context-sensitivity of natural intelligence. This is because the connection weights function as a large number of 'soft constraints,' none of which are individually necessary or sufficient to produce a result. Therefore, connectionist networks can accommodate inputs that are exceptional in various ways, either by ignoring the anomalous aspects or by corresponding adjustment of their output. As a consequence, their performance is also robust in the face of noise in the input or damage to the network. Further, to the extent that microfeatures of the environment are represented in the input, the network can process information in a way that is sensitive to the context. *See* Artificial Intelligence: Connectionist and Symbolic Approaches; Concept Learning and Representation: Models; Connectionist Models of Concept Learning; Knowledge Representation.

Rules and Constituent Structure

Connectionist networks have been criticized for their 'opacity' or 'uninterpretability.' That is, when a connectionist network has been trained to perform some task, it is difficult to extract from the network human-interpretable rules; although the network performs correctly, we cannot see the rules it is apparently following. The reason, of course, is that it is not following rules, and the individual units and weights represent microfeatures and constraints that are lexically meaningless (i.e., have no lexical-level meaning). There are mathematical procedures for extracting rule-like information from networks, but they give only approximations to the network's behavior. This is analogous to what has been observed during knowledge acquisition for expert systems: after the fact, human experts can account in terms of rules for their decision-making, but the rules do not adequately predict the expert's future decisions.

Quite naturally, some of the severest criticisms of connectionism have come from linguists and other cognitive scientists committed to a 'language of thought,' that is, to the hypothesis that cognition must be understood in terms of the manipulation of propositional or sentential symbolic structures. These criticisms have focused on the alleged inability of flat connectionist representations to capture the rich hierarchical symbolic structure of human language and propositional attitudes, and the related sensitivity of cognition to their constituent structure. However, experiments in connectionist symbol processing have shown that connectionist networks can be sensitive to the constituent structure of representations without explicit representation of that structure and without the use of explicit symbolic rules (as in the learning of past tenses). There is much more to the issue than this, however, and the early collection by Pinker and Mehler (1988) is still a good introduction to the anti-connectionist position. *See* Artificial Intelligence: Connectionist and Symbolic Approaches.

Computability

If connectionism is viewed as a fundamentally new approach to information representation and processing, then the question arises of its power relative to conventional digital computation, as modeled by the Turing machine. At one level, this question is easy to answer. On one hand, since connectionist networks are routinely simulated on digital computers, it is apparent that they have no greater power than a Turing machine. On the other hand, researchers have shown that various sorts of connectionist networks can simulate Turing machines, which therefore have no greater power than

the networks. The conclusion would seem to be that connectionist networks are equivalent to Turing machines in computing power.

However, at a different level, the question is problematic, for the Turing machine model is based on certain idealizing assumptions about what is significant and insignificant in models of computation, assumptions that are questionable when applied to connectionist models. In particular, the Turing machine model is based on the assumption that computation proceeds by the recognition of atomic tokens of definite type according to the discrete application of finite, definite rules; these processes are assumed to operate with complete reliability. These assumptions are a poor match to connectionist approaches, in which information is represented in distributed patterns of continuous activity, and in which recognition is a matter of degree. Nevertheless, questions of computability are also important in connectionism, but relevant answers may require the development of a new theory of computation that makes idealizing assumptions more relevant to connectionist approaches.

Relation to Biological Neural Networks

Connectionist networks are often called 'neural networks' and described in terms of (artificial) neurons connected by (artificial) synapses, but is this more than a metaphor? Generally, connectionist models have reflected the contemporary understanding of neurons. For example, McCulloch and Pitts focused on the all-or-nothing character of neuron firing, and modeled neurons as digital logic gates. Newer connectionist models have had a more analog focus, and so the activity level of a unit is often identified with the instantaneous firing rate of a neuron. However, these models still ignore many important properties of real neurons, which may be relevant to neural information processing (Rumelhart et al., 1986, vol. 2, Chapter 20). As a consequence neuroscientists have stressed the differences between biological neurons and the simple units in connectionist networks; the relation between the two remains an open problem. Nevertheless, it is much easier to envision neural implementations of connectionist networks than of symbol-processing architectures.

Another divergence between biological neural nets and many connectionist models arises from the topology of the layers. Although the neurons in a layer may be numbered 1,2,…,N, these labels are arbitrary, and there is no implication that neurons 1 and 2 are any closer together in space than neurons 1 and 3. In the brain, in contrast, many neural populations are organized into 'topographic' or 'computational maps' in which the physical positions of neurons are systematically correlated with properties of some sensory or motor domain (e.g., position on the skin, location is the visual field, edge orientation, sound frequency, reach direction). Neural representations often take the form of spatially distributed fields of activity across these maps, and neural information processing in them depends crucially on spatial relations through such mechanisms as local excitation and lateral inhibition. Some connectionist models incorporate spatial relations, but many do not, and so they might not be adequate models of natural cognitive representations and processes.

Situated Embodiment

Connectionist approaches share a weakness with symbolic computational approaches in that they often treat cognitive processes as computations whose aim is to produce an appropriate output given some input; cognition is treated as an abstract process. However, natural cognition is both situated and embodied.

'Situated' refers to the fact that natural agents are embedded and engaged purposefully in a structured physical environment (often including other agents). The situated approach focuses on the effect that the structure of the environment and the agent's ongoing interaction with it has on the emergent cognitive structures that coordinate that interaction. Therefore, unsituated models, such as many connectionist models, are fundamentally incomplete and unlikely to be able to account for natural cognition. These issues can be addressed by embedding connectionist models into situated robots or sufficiently realistic simulated environments.

Cognition is 'embodied' in the sense, first, that it is implemented by neurophysiological processes, and so connectionist models should take account of that fact (see above). More importantly, however, cognition is embodied in the sense that its principal function is the control of a physical body in its environment. On the one hand, this means that biological neural networks must be capable of controlling in real time the dynamical complexities of living bodies interacting with their physical environments. On the other, it means that a biological control system can exploit the dynamical properties of the body, thereby decreasing the computational load on its nervous system. Both of these are important constraints on the architecture of biological neural networks and on the structure of emergent neural representations – indeed, on the structure of knowledge. Due to its neural orientation and respect for performance issues, connectionism is generally compatible with an embodied approach, but most connectionist models do not address embodiment.

The benefits and limitations of embodiment are investigated in such disciplines as embodied cognitive science and embodied AI; see Pfeifer and Bongard (2007) for a useful review.

Dynamic Systems Approach

The requirements of situated embodiment imply that an adequate theory of cognition must address the real-time control of the coupled dynamics of the body and its environment. However, typical connectionist models incorporate a notion of sequence, but not of time. That is, the network is understood as a functional composition in which each layer of units takes as input, the output of the preceding layer: $y = f_n(f_{n-1}(\cdots f_2(f_1(x))\cdots))$. The network defines the sequence of computations, but not their durations. Some recurrent connectionist networks produce sequences of outputs $y_1, y_2, \ldots$ from corresponding sequences of inputs $x_1, x_2, \ldots$ by feedback of an internal state variable r: $y_i = f(x_i, r_{i-1})$, $r_i = g(x_i, r_{i-1})$. However, such models do not address the essential dynamical, real-time coupling of an agent's nervous system, body, and

environment. To address these issues, the 'dynamic systems approach' views neural networks as dynamical systems and investigates issues such as stability and attractor dynamics that lead to the emergence of representations (e.g., Thelen and Smith, 1994). In particular, dynamic field theory incorporates dynamics and computational maps into connectionism. *See* Classical Mechanics and Motor Control; Motor Control Models: Learning and Performance; Self-Organizing Dynamical Systems.

This article is a revision of the previous edition article by T. Shallice, volume 3, pp. 2128–2133, © 2001, Elsevier Ltd.

Abstract

This article provides an overview of some of the most commonly used methodologies in the discipline of cognitive neuropsychology: dissociations, associations, single case studies, case series, intervention research, computational modeling and the cognitive neuropsychological approach to studying developmental disorders of cognition.

Cognitive neuropsychologists study impaired cognition to inform theories of normal cognition. They do so by observing cognitive behavior in people with impaired cognition, for example, people who have acquired a brain injury. Cognitive neuropsychologists are interested in what data from these individuals reveal about the processes and representations of cognitive systems (McCloskey and Caramazza, 1988).

Dissociations and Associations

Cognitive neuropsychological studies have made major contributions to our understanding of the functional architecture of cognition (e.g., reading: Coltheart et al., 2001; Marshall and Newcombe, 1973; spoken language production: Badecker et al., 1995; Dell et al., 1997; spelling: Miceli and Capasso, 2006; Tainturier and Rapp, 2001). Under assumptions of modularity (Fodor, 1983; see Caramazza, 1992; Coltheart, 1999 for different versions of this assumption), the architecture of cognitive systems is composed of information-processing components that each fulfill a different purpose. These relatively autonomous components can also be independently damaged, for example, as the result of a brain injury. When such a functionally independent component is selectively impaired this will result in a 'dissociation.' Shallice (1988) distinguishes between classical, strong, and trend dissociations. In the most powerful dissociation, the classical dissociation, performance on one task is in the normal range, while performance on another task is very impaired. Strong and trend dissociations consist of less marked differences in task performance. These three dissociations rely on the use of control subjects (who are unimpaired in performing the tasks in question) to determine what score should be considered normal or impaired. John Crawford and his colleagues have provided the statistical means to allow detection of a deficit in a single patient compared to a (relatively small) control group, deliver a point estimate of the abnormality of the patient's score and determine the difference between scores on two tasks (Crawford and Garthwaite, 2006; Crawford and Howell, 1998; Crawford et al., 2009).

An example of an interesting, theoretically important dissociation is that of JOH, who showed an intriguing pattern of performance (Costello and Warrington, 1987). JOH presented with a reading disorder – left neglect dyslexia – that led to reading errors at the beginning of words (e.g., reading *make* as 'cake' or *least* as 'beast'). However, this was not due to a general neglect of the left hand side of space. In fact, he showed evidence of a right-sided visuospatial neglect. That is, when processing (e.g., copying) pictures or figures, he omitted information on the right hand side. For example, when asked to copy a row of three shapes he would omit the last (rightmost) shape. This dissociation shows that there is not a single mechanism underlying neglect in both visuospatial tasks and reading, but rather there are two separate mechanisms, which can be separately impaired.

Note that this dissociation is particularly clear as the argument is not in terms of the extent of the impairment in one task or another (both tasks were impaired) but the type of impairment (reading impaired on the left and intact on the right, visuospatial tasks impaired on the right and intact on the left). In cases where the dissociation is in terms of one task being impaired and the other intact, it could be that this is due to a difference in the difficulty of the two tasks rather than independent mechanisms. For example, interpretation can be open to the potential argument that one task is simply harder than the other (requires more processing resources). Imagine a dissociation between recognition of faces and recognition of printed words. Could it be that this dissociation in fact reflects damage to a single system that impairs face recognition without impairing visual word recognition, because faces are visually more complex, and so stress this system more. However, if there is a case where printed word recognition is impaired and face processing is intact, this would refute the difficulty argument. This pair of opposite dissociations makes up a 'double dissociation,' which has long held to be the strongest evidence for separate processing components.

While cognitive neuropsychology has been accused of being overly interested in dissociations (Laine and Martin, 2012), the study of human cognition often requires testing for associations. Hence, many cognitive neuropsychological studies set out with the explicit aim to discover associations. One example of looking for associations can be found in a multiple single case study on letter position dyslexia (Friedmann and Rahamim, 2007). The main symptom of letter position dyslexia is a disproportionately high number of anagram reading errors (e.g., *slime* read as 'smile'). Friedmann and Rahamim proposed that this error type is caused by an impairment early on in the reading process (the

orthographic visual analyzer). Hence, they predicted that anagram errors should occur in all reading tasks (whether reading of nonwords or words, whether they included reading aloud or not). This association was indeed what they found (also see Section Computational Cognitive Neuropsychology for more examples of studying systematic associations).

Single Case Studies

The investigation of a single case is considered an important (but not the only) methodology in cognitive neuropsychology. Single cases may present with a behavior that cannot be explained by current theories and hence may be used to test, extend, and/or change current understanding in an area of cognition. One of best known single cases to inform cognitive theory is probably that of HM (Scoville and Milner, 1957). The first report of HM has not only attracted over 4000 citations (by 2013) but also has been argued to represent the beginning of the modern study of memory (Squire, 2009). HM was an epilepsy patient who after brain surgery had lost his capacity to remember daily events. At the same time, his intellectual and perceptual functioning remained intact. Before Brenda Milner and her colleagues began to study HM, memory function was thought to be integrated with intellectual and perceptual processes. HM's case helped establish the theory that memory is independent from these other processes.

The main reason why single case studies are considered both powerful and valid rests on the finding that individuals with cognitive disorders are by their nature variable (Caramazza and Coltheart, 2006). Due to the high number of possible functional lesions, there is only a theoretical chance that two patients will ever display the exact same impairment (Caramazza, 1986; Caramazza and Coltheart, 2006; Coltheart, 1984). In commenting on the huge variability in the actual presentation of hemispatial neglect in patients, Buxbaum (2006) evokes the analogy of snowflakes, each of which, of course, is unique. The snowflake analogy is probably valid for most areas of cognition. For example, Schmalzl and colleagues (Schmalzl et al., 2008) studied seven members of a family who had face-processing difficulties (prosopagnosia). These individuals all had difficulties recognizing the faces of family members, four of them could not even identify their own face reliably in a photograph. However, a more detailed investigation showed different underlying impairments for these family members' difficulties in recognizing face. In fact, there were no two family members that showed the exact same pattern of difficulties. For example, some but not all of the family members had difficulties detecting facial expressions. Similarly, some but not all family members had problems detecting when spacing between features of the faces (e.g., nose, mouth) was changed. This is an example of a study that shows how face processing difficulties can be caused by different underlying processes, even within the same family.

Due to this variability, cognitive neuropsychologists tend not to study syndromes. Labels such as prosopagnosia, surface dyslexia, or even Broca's aphasia may be used but they are mere 'short hand' terms for a gross level of symptomatology (i.e., problems recognizing faces; problems reading irregular words; limited syntactic structure in speech production) that hide the complexity of each patient's presentation and the high variability between patients. Studying the average performance of groups of patients that belong to the same syndrome complex could mask important differences between individuals as well as produce averages that do not describe a single individual in this group. However, single case studies have been criticized for their lack of generalizability, lack of control, and poor statistical methods (but see e.g., Robey et al., 1999). Lack of control and statistical problems are easily taken care of by using appropriate designs including converging evidence from replications, multiple experiments of the function in question, and employing some of the myriad of appropriate statistics (e.g., McNemar's, Fisher's exact, Wilcoxon). Generalizability can be improved by studying symptoms (rather than syndromes) in multiple single cases (Friedmann and Rahamim, 2007; Warrington, 1975). Indeed, many reports of new dissociations within a syndrome describe multiple cases, which are examined for their differences and similarities in performance; both in reference to previous cases and within the sample reported in the new paper.

If patients are so highly variable in terms of their functional deficits, how is it ever possible to generalize beyond the level of the individual? This relies on two assumptions. First, the assumption of 'universality' poses that neurologically intact people do not differ from each other in regard to their cognitive architectures (Caramazza, 1986). It is worthwhile to note that this assumption underlies all studies of cognitive psychology, otherwise inferences about cognition could not be made from small study samples drawn from the general population. Moreover, some degree of individual difference is not incompatible with the universality assumption (Rapp, 2011). Second, if inferences can be drawn from neurologically impaired patients to normal cognition, it needs to be the case that the injury simply subtracted one or more cognitive functions without also altering or adding new functions (Saffran, 1982). Therefore, studying an individual with a selective impairment provides a unique experimental technique for studying human cognition, in particular, a system that misses exactly one function. However, single case studies are only one of the methodologies available to the cognitive neuropsychologist.

Case Series

Another form of study with multiple participants that is popular in cognitive neuropsychology is the case series (Schwartz and Dell, 2010). McCloskey and Caramazza (1988) distinguish between two ways of studying groups of people: *Group studies*, which report average performance of the group in a way that individual results are invisible vs *case series*, in which individual data for each participant are reported. Averaging is only appropriate when variability in the data is assumed to be due to noise (McCloskey and Caramazza, 1988). As noted above, one of the problems in reporting agglomerate data in classical group studies is that what describes the whole group may not describe any single individual. Case series do not suffer from this problem. Case

series designs have the potential to allow the identification of central tendencies in the data, which reflect the actual performance of several individuals, while still including variability typical of larger populations (Shallice and Buiatti, 2011).

In patient data, heterogeneity may be informative in that it may reveal systematic relationships among different variables (Schwartz and Dell, 2010). While heterogeneity in the dependent variable is required to carry out such investigations, it is important that the source of the variability is relevant to the question in hand (Nickels et al., 2011). For example, when investigating word retrieval in a group of aphasic speakers, the individuals should vary in terms of their naming accuracy. At the same time, factors that could potentially impact on performance on the dependent variable (e.g., picture naming), but are not subject of the particular investigation, such as attention or object recognition need to be kept similar between the individuals. Which exact variables need to be kept similar and which should vary depends on what theory a study aims to investigate.

There are certain theoretical questions that require a case series methodology. Rapp (2011: p. 437) summarizes them as "As X increases (or decreases), Y should increase (or decrease)." Hence, the study would select patients with varying degree of deficits in skill X and test their ability to do Y. Rapp's examples of X and Y include the severity of a semantic impairment and accuracy for exception word reading (Woollams et al., 2007); or severity of sublexical damage and perseveration errors in spelling (Fischer-Baum and Rapp, 2012). Note that all of these studies are interested in a theoretically relevant association between two functions.

Ideally, case series should include a combination of standard background assessment and experimental tests. These should be performed on all participants in a case series and also take into account items and tasks that have been used in previous studies (Nickels et al., 2011). Using similar tasks and items not only makes it easier to compare cases across studies but also helps in testing and designing computational models of cognition.

Computational Cognitive Neuropsychology

The architecture of cognitive processes is often described in verbal or diagrammatic models. These consist of verbal descriptions or box and arrow type diagrams. Seidenberg and McClelland (1989) were the first to design a computational model of reading aloud. Since then, more cognitive theories have been implemented computationally, including one of the most well-known reading models, the Dual Route model (e.g., implemented as the Dual Route Cascaded model: Coltheart et al., 2001), but also models of spelling (e.g., Houghton and Zorzi, 2003) and spoken language (Dell et al., 1997; Levelt et al., 1999; Roelofs, 1997). A good model, be it verbal, diagrammatic, or computational, should be able to account for the full body of evidence pertaining to both normal and impaired cognition.

Cognitive neuropsychological principles can also be applied to these computational models. They can be 'lesioned' in order to display symptoms described in patients (Coltheart, 2006). Lesioning a model can be achieved in different ways, depending on the model. For example, the strengths of connections can be adjusted or noise may be introduced. Whatever change to the 'normal' computational model best fits the patient data, can be regarded as an account of the type of impairment to the cognitive system. Damaging a computational model in ways that will match the data of patients can provide converging evidence for a certain theory, and it can also allow a specification in how exactly cognitive processes are impaired when a certain pattern of impairment is shown.

Case series (see Section Case Series) can play a great role in testing these models. Nickels (1995) examined the errors produced in picture naming by a case series of people with aphasia. Specifically, she examined the relationship between production of semantic (doctor named as 'nurse') and phonological (doctor named as 'doptor') errors and the psycholinguistic variables that affected these errors. Imageability was found to affect the production of semantic errors (but not subjective frequency, or length). Whereas for phonological errors subjective frequency and number of phonemes showed significant effects (but not imageability). Nickels used these patterns to adjudicate between the predictions of highly interactive and strictly feedforward models, arguing that the data were inconsistent with the interactive models of speech production.

Theoretical Impact of Treatment Studies

In its aim to understand human cognition, cognitive neuropsychological studies can assess patients' performance on a multitude of tasks pertaining to the area of cognition under investigation. One way to adjudicate between different theories of cognition is to design an experiment in which different theories predict different outcomes. The experimental design can be an intervention. Hence, another powerful tool to test theories is the use of treatment (Nickels et al., 2010). For example, Biedermann and Nickels (2008a,b) investigated the lexical representation of homophones using treatment (see Nickels et al., 2010 for other examples of studies using intervention to investigate cognitive theories). Homophones are words that are pronounced in the same way but have different meanings (e.g., tank: fish-tank, military tank; flour/flower). One theory proposes that each version of a homophone has its own lexical representation (Caramazza, 1997), while an opposing theory posits homophones share a representation (Levelt et al., 1999). Biedermann and Nickels designed an intervention study to provide new insights into this debate. Intervention can help people with word finding difficulties to become better at retrieving the words practiced during intervention. However, usually, effects are restricted to practiced words and will not benefit words that were not explicitly practiced during the intervention. Following this logic, Biedermann and Nickels made the following differential predictions: if homophones share representations, treating one partner of a homophone (e.g., flower; (fish) tank) should lead to improvements in retrieving the untrained partner of the homophone (i.e., flour; (military) tank). In contrast, if

each homophone partner has its own lexical representation, only the trained words (e.g., flower; (fish) tank) should improve. The results favored the theory that homophones share lexical representations since not only the trained homophones but also their untrained partners improved after training. Note that a set of control words that sounded similar to the treated words (but were not homophone partners) or were similar in meaning did not improve.

Other than providing insights into theoretical issues cognitive neuropsychological approaches to treatment can be used to assess the efficacy of treatment protocols and procedures. Moreover, there are many examples of treatment studies where the aim was to explain how a particular treatment works within a particular cognitive architecture. Often, these explanations in effect provide converging evidence for one particular theory. An example of this is a treatment study conducted with a person who had both deep dyslexia and anomia (Nickels, 1992; see Nickels et al., 2010 for further examples). Deep dyslexia refers to impaired reading that is marked by the presence of semantic reading errors (e.g., reading *wine* as 'beer'), visual errors (e.g., *late* as 'lake'), morphological errors (e.g., *swims* as 'swimming'), a word class effect (i.e., function words worse than content words), and an inability to read nonwords. Nickels' participant TC also made many semantic errors when asked to name pictures. The intervention consisted of reteaching letter–sound correspondences. While this did not lead to improved nonword reading (because the participant remained unable to blend sounds together to form a word), the frequency of semantic errors decreased after intervention. These results were later used as supporting evidence for the 'summation theory' according to which phonological information feeds back into the phonological lexicon (Hillis and Caramazza, 1995). After the intervention, TC started to 'self-cue' by using his knowledge of the initial letter of a word he was supposed to say and generating the sound (Nickels, 1992). For example, if he was asked to name the picture of a *tiger*, TC would activate semantically related words in addition to the correct word (e.g., leopard, panther, tiger, lion). Being able to retrieve the written word form, and sounding out the initial letter T, provided additional activation to the correct response allowing selection, and reduction of semantic errors.

The cognitive neuropsychological approach to intervention also advocates that, with use of a strong design and appropriate statistics, single case intervention studies can provide a high level of evidence for the efficacy of treatment. Many cognitive neuropsychologists would argue, once again, that a series of single case studies can provide stronger and more valid evidence than evaluating average effects over a group study (such as advocated in randomized controlled trials) (also see Wright, 2012 for a discussion of this issue).

Acquired and Developmental Cognitive Neuropsychology

Traditionally, the cognitive neuropsychological approach has been applied to studies with individuals with acquired disorders, that is, people who are now impaired in a skill that they had fully acquired prior to their brain injury. However, in the 1980s, the methodologies of cognitive neuropsychology were extended to the developmental domain, where a cognitive system is still in the process of being acquired. This work was pioneered by John Marshall, Jane Holmes, and Christine Temple. Developmental cognitive neuropsychology investigates developmental disorders using models of the cognitive architecture of the adult system. The strong claim underlying this approach is that in developmental disorders, highly selective disorders should be observable (Castles et al., 2006; Marshall, 1984; Temple, 1997). This is in contrast to a view according to which a disorder early in development distorts the system in more than one way since development is an interactive process (see Bishop, 1997). For example, if a child has difficulties learning to say words, they may also have difficulties to learn the sounds of a language. The degree to which development of different cognitive functions happens independently is an ongoing topic of research. However, there is now a large literature detailing the vast differences in the presentation of children with developmental dyslexia (see Castles et al., 2006; Marshall, 1984): for almost every processing component in the reading architecture (in this case dual route models of reading), there are published case reports of developmental cases who have a specific difficulty acquiring the skill that is governed by this processing component (for overviews of these disorders see Coltheart and Kohnen, 2012; Jones et al., 2011). These selective difficulties can be taken as evidence that development of cognitive skills can, to some degree, be modular.

In the case of developmental dyslexia, cognitive neuropsychologists refer to dual route architecture. Evidence for this architecture is based on data from adult readers. Hence, one could call dual route models 'adult models' of reading. What is somewhat controversial is whether developmental disorders should be studied within the framework of an adult system; a cognitive system that is presumably static and not learning and developing. Bishop (1997) argues that the course of development is typically highly interactive, with skills and competencies influencing each other. Therefore, children usually present with complex patterns of associated impairments, rather than highly selective deficits. While pure cases of selective difficulties do indeed tend to be rare (Castles et al., 2006), they nevertheless make contributions to our understanding and advance developmental theories of cognition. For example, one of the most prominent current theories of how children acquire a written vocabulary posits that lexical acquisition depends largely on nonlexical skills (Share, 1999). After one or more exposures where a novel word is sounded out using nonlexical skills, a representation of the word will be developed in the orthographic lexicon. However, some children acquire a reading vocabulary that is at a normal level while their nonlexical skills are severely impaired. This is called developmental phonological dyslexia. While Share's theory is plausible, it is cases of phonological dyslexia that clearly show that this theory alone cannot explain how children acquire a reading vocabulary. This is just one example of how the study of selective deficits in developmental disorders is important in furthering our understanding of the acquisition of cognitive functions.

Conclusion

Cognitive neuropsychology aims to understand and uncover the cognitive architecture and processing that underlies both normal and impaired cognition. It does so by studying children and adults with cognitive disorders, or lesioning computational models of cognition. Note that many of the methodologies described above are not only used by cognitive neuropsychologists. For example, single case studies form an important methodology in medical science. Similarly, the use of treatment studies to inform theory is also used in many other disciplines, including, for example, in developmental psychology. Embracing multiple methodologies is one way to further understanding of human cognition and ultimately the interaction of brain and mind.

Abstract

Cognitive neuroscience explores the neural basis of cognition, including perception, attention, language understanding, memory, problem solving, and decision-making. The field draws on findings on how neurons process and represent information, and on ideas about how learning may occur through the modification of properties of neurons and their connections. It is clear that there is specialization of function in the brain, yet brain areas appear to work together, interactively, to support emergent cognitive functions. The article discusses these points, reviews research methods used in this field, and touches on open questions, as well as the future of cognitive neuroscience.

What is the neural basis of cognition? How do our thoughts, perceptions, beliefs, and intentions arise from the activity of the vast numbers of neurons in the brain? The discipline of cognitive neuroscience emerged in the 1990s at the interface between neurobiological, cognitive, and computational sciences to answer these questions. On one side, the discipline grows out of the traditions of both cognitive psychology and neuropsychology, which use behavioral experiments to uncover the processes and mechanisms underlying normal and impaired human cognitive processes, linking work of this kind to computational modeling approaches to develop explicit mechanistic accounts of these functions and dysfunctions. On the other side, it emerges from the traditions of neuroscience, which use neurophysiological and neuroanatomical methods to explore the mechanisms underlying complex functions and draws on findings and principles of cellular and molecular neuroscience. It joins these approaches with the use of both structural and functional brain imaging methods, and the application of formal mathematical models (computational neuroscience) to explore how neural processes give rise to cognitive outcomes.

The Microstructure of Cognition

Patterns of Activity Arising in Ensembles of Simple Elements

A starting point for cognitive neuroscience is the idea that a cognitive or mental state consists of a pattern of activity distributed over many neurons. For example, the experience of holding, sniffing, and viewing a rose is reflected in a complex pattern of neural activity, distributed over many brain regions, including the participation of neurons in somatosensory, olfactory, and visual regions, and possibly extending to language areas (that represent the words we use and hear in relation to this object) and other neural regions that code information associated with the experience.

These patterns of activation arise from excitatory and inhibitory interactions among the participating neurons, mediated by connections called synapses. The inputs that neurons receive cause them to 'fire' or emit electrical pulses, called spikes or action potentials, which travel down their axons to synaptic terminals where they cause the release of chemicals (neurotransmitters) that then have excitatory or inhibitory influences on the neurons on the other side of the synapse. The combined effect of the incoming signals to each neuron, together with its recent history, determines whether it will fire at a particular moment. Figure 1 indicates something

Figure 1 An early camera lucida drawing of the circuitry of the neocortex, based on the Golgi stain method, which impregnates just one out of every 100 cortical neurons. The diagram depicts the rich dendritic branching structure of the individual neurons present, whose cell bodies appear as small, pyramid-shaped blobs. The dendrites (and the little spines visible on the surfaces of some of the larger dendrites) are the structures on which the neurons receive most of their inputs from other neurons. This figure comes from a book by the Spanish neuroscientist Santiago Ramon y Cajal. I recently retrieved it from Wikimedia Commons on 2009-11-20. It was originally published in Santiago Ramon y Cajal 'Comparative study of the sensory areas of the human cortex' published 1899, ISBN 9781458821898. I believe it is in the public domain.

of the fundamental circuitry involved, though it should be noted that only one out of 100 of the neurons in the tiny region shown (about 1×1 mm) are indicated, and the synaptic connections onto the neurons illustrated are not visible. While the computations performed by individual neurons should not be underestimated (*see* Neurons and Dendrites, Integration of Information in), it seems likely that what gives the system its power and complexity is the number of neurons involved (most estimates place the number in the human brain between 10 and 100 billion) plus the density and pattern of connections among them (typical cortical neurons receive between 10 000 and 100 000 individual synapses from other neurons).

Distributed Representations

A great deal of research has concerned the nature of the active representations that the brain uses (cf rose example above). There is now a great deal of support for the view that the brain's representations typically consist of activity patterns involving many thousands or millions of neurons. Individual neurons are often described as 'detectors' for particular stimulus or situational features or conjunctions of features (e.g., the 'edge detectors' introduced by Hubel and Weisel (1962) in their seminal studies in visual cortex), but most such neurons are fairly broadly tuned, so that they will also be partially activated by a wide range of stimuli overlapping in one way or another with the optimal stimulus, and thus will participate at least partially in the representation of many different inputs.

A prime example of distributed representation is that of the direction of arm movements in the motor cortex. It appears that the representation of a particular direction of reaching reflects a pattern of distributed activity over a large population of neurons, each of which responds maximally to a particular preferred direction, but responds to a lesser degree to neighboring directions, and thus participates partially in the representation of many different directions of reaching (Georgopoulos et al., 1986). There are other types of distributed representations used in the brain, in which a neuron can participate in two different representations, without there being a clear shared feature or other similarity between the situations that cause the neuron to fire. For example, in the hippocampus, individual neurons participate in distributed representations of the animals' location in external space and other aspects of the current behavioral situation. Interestingly, the same neurons may participate in different ways in the representation of different environments, or even of two distinct representations of the same environment when the animal performs different tasks (Markus et al., 1995). Some studies suggest that there may be neurons specialized for items or persons who are highly familiar (e.g., a current actress frequently described in the popular media, Quiroga et al., 2005).

Knowledge and Learning in the Strengths of Connections

The particular pattern of activation that arises in experiencing an input (or in reconstructing a memory or formulating an imagined experience) is determined by the connections among the neurons. A key issue, then, is to understand the processes that lead to the formation of the specific excitatory and inhibitory connections that shape the processes of perception, cognition, and action. Generally, it is thought that largely activity-independent processes establish an initial skeleton framework of connectivity early in development, for example, causing connections to form between neurons in the retina of the eye and other neurons in the lateral geniculate nucleus, a way station for visual information on the way to the cortex. Then, activity-dependent processes selectively refine and stabilize some of the connections, and perhaps cause new ones to form, while other connections are pruned away.

Activity-dependent processes continue throughout life, at least in many parts of the brain, and appear to provide the basis of both explicit and implicit learning. They have been the subject of intense scrutiny in neuroscience. Donald Hebb, the mid-twentieth-century neuropsychologist, proposed that if one neuron participates in firing another, the connection from the first to the second will be strengthened (Hebb, 1949). Hebb's idea has been encapsulated in the phrase 'cells that fire together wire together.' While there is no direct proof that this is a principle of learning in the brain, the idea has received a great deal of experimental support in experiments that have been carried out in slices of brain tissue (*see* Neural Plasticity). It should be understood that there may also be plasticity at the level of the whole neuron (in some specialized brain areas, neurons are continually created and incorporated into circuits while others are continually being lost). There is also likely to be some plasticity at the level of the branches of axons and/or dendrites, which provide the scaffolding underlying the formation and loss of synaptic connections.

System-Level Organization: The Macrostructure of Cognition in the Brain

Specialization of Brain Regions

A central and important fact about the organization of cognition in the brain is that individual brain regions are specialized. The cerebral cortex can be partitioned conceptually into primary, secondary, and tertiary cortical zones (Luria, 1966). According to this conception, the primary areas contain neurons whose responses can be largely characterized as reflecting relatively simple, local properties of inputs or outputs within a given modality, such as the presence of an oriented line segment at a particular position on the retina of the eye, the presence of acoustic energy in a particular frequency band, or the presence of a tactile stimulus at a particular point on the skin surface. Corresponding motor areas contain neurons whose responses may correspond to the activation of specific muscles or elementary movement elements. Secondary areas contain neurons whose responses represent higher order stimulus attributes within a given modality, such as conjunctions of features, and the representations in these areas may be relatively invariant over some lower level properties, such as position of the stimulus containing the feature on the sensory surface (Tanaka, 1996). Tertiary areas are responsible for representations that transcend individual modalities, such as representations of the current task context, representation of one's location in extrapersonal space, or representation of semantic content. It should be noted that this picture is only a very crude approximation, and many so-called primary areas appear to participate in the representation of the global

structure of a stimulus or response situation, and many areas that are treated as modality-specific can be modulated by influences from other modalities (see below). It should also be noted that structures outside the neocortex also play very important roles in cognitive functions. Among these are the diffuse neuromodulatory systems that regulate behavioral/cognitive states such as alertness, wakefulness, and mood; and subcortical systems in the thalamus, basal ganglia, and cerebellum that play important roles in sensory motor processes, skills and habit formation, and motor learning. The amygdala plays a central role in emotion and its influence on cognition, and the hippocampus plays a crucial role in the formation of new memories.

Modular versus Interactive Approaches to the Organization of Function

The mechanisms and processes noted above provide only the starting place for the formulation of an understanding of how cognitive processes arise from neural activity. There are two contrasting views: (1) The modular approach, championed by David Marr for vision and Noam Chomsky for language, and systematized as a general approach to understanding brain organization by Fodor (1983), holds that the brain consists of many separate modules that are informationally encapsulated in that their operation is informed only by a very limited range of constraining sources of information. The modular view also holds that the principles of function are specific to each domain, and that distinct and individualized mechanisms are used to subserve each distinct function. For example, the initial assignment of the basic grammatical structure to a sentence is thought to be based only on the syntactic classification of words and their order, and to be governed by the operation of a system of structure-sensitive rules. The module that carries out this assignment is considered to be structured specifically so that it will acquire and implement structure-sensitive rules, and to contrast in the principles that it employs internally with other modules that carry out other tasks, including other aspects of language processing, such as the assignment of meanings to the words in a sentence. In Fodor's view, there are many specialized modules (corresponding approximately to primary and secondary cortical areas and their subcortical inputs and outputs). These are complemented by a general-purpose cognitive system that is completely open-ended in the computations that it can undertake and in the range of informational sources that it can take into consideration.

The alternative, interactive approach, has its seeds in the ideas of Luria (1966), and has been championed by Mesulam (2000) and Rumelhart et al. (1986), and overlaps with the ideas of Damasio (1989). On this view, cognitive outcomes, such as the assignment of an interpretation to a sentence, arise from mutual, bidirectional interactions among neurons in populations representing different types of information. An example of a system addressing the representations and interactions involved in reading individual words aloud is shown in Figure 2. As the Figure suggests, the formation of the pronunciation from a visual orthographic input arises from an interactive process involving orthographic (i.e., letter identity), semantic, phonological, and contextual information. Both the modular and the interactive view are consistent with the idea that neurons in the brain are organized into populations

Figure 2 The interactive, distributed framework for modeling individual word reading of Seidenberg and McClelland, 1989. All of the relevant processing pathways are assumed to be bidirectional. Figure 2 comes from Figure 1, p. 526, of Seidenberg, M.S., McClelland, J.L. 1989. A Distributed, Developmental Model of Word Recognition and Naming. Psychological Review 96, 523–568. Copyright 1989 American Psychological Association. Reprinted with permission (automatically granted by APA for a single figure).

specialized for representing different types of information (though the degree of specialization remains hotly debated; see Kanwisher, 2010). Where they differ is in the extent and the role of bidirectional interactions among participating brain areas and in the extent to which the principles governing computation in each area are domain-general or domain-specific.

Evidence of Interactive Processes in the Brain

The debate between modular and interactive approaches is a long-standing one, and can be seen as the modern legacy of a history of diverse views on the localization of functions within the brain (Luria, 1966). While the debate is likely to continue to evolve with additional empirical evidence, it may be worth considering a few elements of evidence that support the idea that processing may be interactive. One relevant anatomical point is the fact that connectivity within and between brain areas is generally reciprocal: when there are connections from region A to region B, there are nearly always return connections (Maunsell and van Essen, 1983).

While there is no consensus on the function of reciprocal connections, there is some evidence that they subserve distributed, interactive computations, at least in particular cases. For example, there is evidence that interactive processes influence the activation of individual neurons in primary visual cortex (Area V1). Traditionally, individual neurons in this area have been seen as encoding the presence of segments of oriented edges at particular positions in a visual display. Recent evidence suggests, however, that primary visual cortex participates in a distributed and interactive process that contributes to the representation of global stimulus properties such as figure-ground organization. The firing of neurons in primary visual

cortex is strongly affected by temporary inactivation of corresponding portions of secondary visual cortex, suggesting that reciprocal interactions between these areas shape neuronal responses in V1 (Hupe et al., 2001). Although the initial response of neurons in V1 is determined by appropriate oriented line segments at a specific location, by about 80 ms their firing is heavily dependent on the global structure of the display (Lee et al., 1998). Furthermore, neurons in V1 respond to illusory contours (contours that are not present in the image but are implied by other contours and perceived by the viewer) that fall in their receptive field. The response occurs at a lag of about 80 ms, suggesting an indirect source, perhaps arising from feedback from higher cortical areas (Lee and Nguyen, 2001). There is also considerable evidence of between-modality interactions. For example, activity in auditory processing areas associated with speech perception is enhanced by visible speech (Callan et al., 2001). There are many corresponding examples of cross-modal influences in single neuron recording studies in animals.

Methods and Approaches in Cognitive Neuroscience

Cognitive neuroscience is a highly interdisciplinary endeavor and draws on a wide range of research methods and approaches, each with its own history and underlying theoretical frame of reference. One important challenge for the field is to find ways of integrating the insights gained from the different methods to allow the field as a whole to converge on a common theoretical framework. Here the predominant research approaches are briefly described, and some of the prospects for integration are considered.

Lesion and Behavior Approaches (Cognitive Neuropsychology, Behavioral Neuroscience, and Transcranial Magnetic Stimulation)

These research approaches have the oldest historical roots, based as they often are in the assessment of the effects of naturally occurring brain damage on cognitive function. A seminal case study was the report by Broca (1861) of a man with a severe disturbance of language arising from a large brain lesion in the posterior portion of the left frontal lobe. Since Broca's day, neurologists and neuropsychologists have investigated the effects of accidental or therapeutic brain lesions in humans, and many key insights have arisen from these studies (*see* Agnosia; Amnesia: General; Aphasia; Dyslexias, Acquired and Agraphia). The subdiscipline of cognitive neuropsychology arose specifically around the study of the effects of brain lesions (*see* Cognitive Neuropsychology, Methods of). A complementary endeavor has grown up around the use of brain lesions in animals carried out with specific experimental intent. This tradition is relevant to human cognitive neuroscience in view of the very close homology between many structures in the human brain and corresponding structures in the primate and rodent brains. This work has obvious advantages in that lesions can be carefully targeted to particular brain areas to test specific hypotheses. Many key insights have emerged from this work, including the discovery of complementary processing streams in the visual system (Ungerleider and Mishkin, 1982; *see* Neural Plasticity). A third technique, which shares many of the same features, is transcranial magnetic stimulation (TMS). TMS utilizes a high magnetic field to generate stimulation in the cortex immediately below the coil. When combined with careful behavioral experiments, TMS can be used to test the role of targeted (human) brain regions. Unlike human neuropsychology, of course, the transiently stimulated brain regions are under experimental control not only in terms of location but also the timing of the interference. Consequently, both the function and the chronometry of brain regions can be probed (Walsh and Cowey, 2000). While all three techniques have provided important and fundamental insights about brain function, the approaches are not without their pitfalls, since lesions or localized stimulation may have unintended and unobserved effects in other brain regions; the refinement and extension of experimental lesion techniques is ongoing (including the combination with functional neuroimaging).

Neuronal Recording Studies

Studies relying on microelectrodes to record from neurons in the brains of behaving animals can allow researchers to study the representations that the brain uses to encode information and the evolution of these representations over time. Several fundamental observations have been made using this technique. As discussed above, these studies indicate, among other things, that the brain relies on distributed representations and that neurons participate dynamically and interactively in the construction of representations of external inputs. As one example, neuronal recording studies have had a profound impact on our understanding of the nature of representations of extrapersonal space. There are neurons in the brain that encode the location of objects in extrapersonal space simultaneously in relation to many different parts of the body, including the limbs and head (Duhamel et al., 1991; Graziano and Gross, 1993) and other neurons that encode the locations of objects in relation to other objects (Olson and Gettner, 1995). Furthermore, recordings from neurons in parietal cortex suggest that when we move our eyes from one location to another, we update our internal representations of the locations of important objects in space, based on where we anticipate that they will be after the upcoming eye movement (Duhamel et al., 1992).

An important recent development is the ability to record from hundreds or thousands of individual neurons at a time. A key finding that has come out of this work is the confirmation in studies with rodents that the simultaneous and successive patterns of activity acquired during behavior may be reactivated in the brain during subsequent sleep (Wilson and McNaughton, 1994). The potential of such methods to shed light on the moment-by-moment relations between activations of different neurons and between distributed brain representations and specific inputs and outputs makes them essential to the future of cognitive neuroscience.

Although primarily utilized in nonhuman situations, some important findings have arisen from the rare opportunity to measure directly from the human cortex. As a part of preoperative neurosurgical investigations, some patients have subdural grid or depth electrodes inserted. In addition to providing key clinical information (e.g., localizing important language and motor functions, or epileptic foci), these studies have generated direct insights about the location of human cognitive functions (including language), and about the timing of the underlying neural activity and interactivity between regions. For example, although often considered to be a high-order component of the visual 'ventral stream,' these methods have shown that the anterior fusiform/inferior temporal gyrus region is important in human language function (the 'basal temporal language area': Lüders et al., 1991) and can probe the presence and timing of cortico-cortical connectivity (Matsumoto et al., 2004).

Functional and Structural Brain Imaging

Cognitive neuroscience arose as a distinct discipline at the same time as the emergence of functional brain imaging methods (PET, fMRI, EEG, and MEG) as major tools for the analysis of human cognition. Indeed, the prospect of visualizing human cognitive activity has been a major catalyst for the field. First used to analyze cognitive functions by the St Louis group (Petersen et al., 1988; *see* Functional Brain Imaging), these methods have come into widespread use. While these methods have low temporal and spatial resolution compared to neuronal recording studies, they still provide our best opportunity to explore the neural mechanisms underlying distinctly human cognitive functions.

The broad adoption of functional neuroimaging techniques since 1988 means that a vast array of methods and findings has emerged from this part of cognitive neuroscience (Bandettini, 2012). The full range of cognitive functions spanning from perception to higher cognitive functions including language, social interaction, and consciousness have been explored using these methods. The first and still very common use of functional neuroimaging is to localize function often with an aim to corroborate findings from other methods, and/or to explore commonalities and differences in human and animal brain organization. As an obvious extension to classical neuropsychology, such approaches have the advantages that, depending on the imaging technique, function can be probed across the entire brain simultaneously and for 'normal' function. Consequently, studies are not confined either to the limited number of recording locations offered with single cell recording or to the neural locations implicated by neurological disease or TMS. In addition to this, brain imaging has begun to reveal a great deal about the plasticity of the brain, since patterns of brain activation can change dramatically with practice (Karni et al., 1998) or after brain damage (Saur et al., 2006). The counterpoint limitation of functional neuroimaging, however, is the method does not identify which region(s) are necessary for that function – something that can only be derived from neuropsychology and TMS (Price and Friston, 2002).

As noted above, at the heart of cognitive neuroscience has been a debate between modular and distributed approaches to understanding human cognition. These same themes are apparent within functional neuroimaging. Thus, the early and still common use of the 'subtraction method' in neuroimaging (where brain activity for a specific cognitive component is identified by contrasting target and control activities that utilize the same assumed cognitive elements minus the key cognitive component) is based, at least implicitly, on a version of a modular view of brain function, which may be incorrect for a variety of reasons (Price and Friston, 2002). Functional neuroimaging, however, has tended to support a more distributed approach given that studies of cognitive function almost never elicit a single region but rather a broadly distributed 'network' of cortical and subcortical areas. Thus, more recently, alternative acquisition and analysis methods have been adopted, which consider cognitive function to be inherently distributed in nature either at whole brain or local levels. At the whole-brain systems level, many studies explore or extract the pattern of correlated activity across a set of regions from either spontaneous ('resting state') or task-based brain activity (referred to as 'functional connectivity') or investigate how the relationship between brain regions changes with respect to task- or stimulus-related factors ('effective connectivity'). At the local level, other approaches have adopted the principle that representations are likely to be distributed and may generate only small variations in local activity (i.e., within $\sim$1 mm^2 *voxels*) in keeping with multielectrode neurophysiological studies (see above). Accordingly, multivoxel pattern analyses investigate the pattern of activity observed across a patch of cortex in order to reveal how different types and levels of information for a set of stimuli are neurally coded (Kriegeskorte, 2011).

In addition to the investigations of neural function, neuroimaging techniques also provide important information about the anatomy of the brain. Indeed, before the advent of neuroimaging, attempts to relate patients' impairments to the pattern of underlying damage (neuropsychology) or investigations of the white-matter connectivity of the human brain were limited to postmortem studies. Modern structural neuroimaging has provided a method for investigating neuroanatomy in ever-increasing detail such that with high-field scanning and analysis methods, it is now becoming possible, for example, to image the layered structure of cortex in the living human brain (*in vivo*). This technological shift provides multiple novel opportunities for cognitive neuroscience including: (1) the ability to relate function and dysfunction (after brain damage or in neurodevelopmental disorders) to brain structure not only *in vivo* for each individual but across a much larger sample of individuals than is practically possible for postmortem studies, licensing correlational as well as intergroup comparisons (e.g., voxel-based lesion-symptom mapping: Bates et al., 2003); (2) the opportunity to map the white-matter connectivity between neural regions including the major long-distance neural pathways or *fasciculi*, and relate these to function and dysfunction; and (3) emerging possibilities to map subtle anatomical features of different brain areas *in vivo*.

Computational and Mathematical Modeling Approaches

While investigations relying on lesion and behavior approaches, neuronal recording studies, and functional brain

imaging have provided and will continue to provide the empirical evidence on which to build our understanding of the basis of cognitive functions in the brain, these approaches, even when used in a convergent way, may still fail to provide a complete understanding of how cognitive functions emerge from underlying neural activity. This may require the use of additional tools provided by mathematical modeling and computer simulation. These approaches allow researchers to formulate possible accounts of specific processes in the form of explicit models that can be analyzed mathematically or simulated using computers to determine whether they can account for all of the relevant neural and behavioral evidence. In short – like other sciences – purely analytical techniques are insufficient to build a true understanding, instead it is important to test and refine theories through synthesis.

Three examples of cases in which computational models have already led to new thinking will be briefly considered. First, a number of computational modeling studies have shown that many aspects of the receptive field properties of neurons and their spatial organization in the brain can arise through the operation of very simple activity-dependent processes shaped by experience and a few rather simple additional constraints (Linsker, 1986; Miller et al., 1989; *see* Neural Development: Mechanisms and Models). Second, models may aid in the understanding of the pattern of deficits seen in patients with brain lesions. Certain patients with an acquired dyslexic syndrome known as deep dyslexia make a striking type of error known as semantic errors; for example, the patient may misread *apricot* as 'peach.' In addition, all such patients also make visual errors, for example, reading *sympathy* and 'symphony.' Early, noncomputational accounts postulated that there must be multiple lesions underlying this disorder. However, computational models of the reading process (Hinton and Shallice 1991; *see* Cognitive Functions (Normal) and Neuropsychological Deficits, Models of) have shown that a single lesion affecting either the visual or the semantic part of an interactive neural network will lead to errors of both types. Thus, the coexistence of these errors may be an intrinsic property of the underlying processing architecture rather than a reflection of multiple distinct lesions. A third area where computational models have shed considerable light is in the interpretation of the receptive field properties of individual neurons (Zipser and Andersen, 1988). While initial interpretations were based on verbally describable features such as oriented bars or edges, such properties are not always apparent, and even when they are, a more detailed characterization may be possible in computational terms (Pouget et al., 1999). A further area of fertile research is in the use of computational models to explain and catalog the ways in which neuronal activation changes dynamically in the course of task performance (Moody et al., 1998).

Like all single methodologies in cognitive neuroscience, an important future step will be the fusion of computational and mathematical models with complementary neuroscience methods. Computational models have the capacity to include and test the implications of new findings at different levels of analysis, ranging from cellular/molecular influences on neuronal assemblies through to the question of how sophisticated high-order human cognition arises from interactions between widely distributed, interconnected cortical and subcortical regions. Perhaps even more excitingly, computational models may offer a formal mechanism to bridge between these different levels of analytical neuroscience (Ueno et al., 2011), ultimately offering a tangible link between brain and mind, which is the central, essential goal of cognitive neuroscience.

Open Issues in Cognitive Neuroscience

Cognitive neuroscience is young, and there is a great deal of work to be done. No aspect of cognition is fully understood, and in general, the more abstract or advanced the cognitive function, the less is known about its neural basis. A few of the most important and interesting issues that remain to be addressed are considered briefly here.

How Does the Brain Learn?

There is a great deal known about the basic mechanisms of synaptic plasticity, but typically these are studied in highly reduced preparations, such as brain slices. The basic processes that are studied in slices surely play a role in the shaping of neural connections in the whole, living brain, but they are also undoubtedly modulated by processes that are usually eliminated in slices. We know that attention and engagement in processing is essential for learning, and there is good reason to believe that learning is gated by various neuromodulatory mechanisms in the brain, but the details of the modulation and gating processes are only beginning to be explored.

What Makes an Experience Conscious?

Although some considerable progress has been made in characterizing the concomitants of consciousness (*see* Consciousness, Neural Basis of), there is no overall understanding of exactly what it is about the activity of the brain that gives it the attribute of consciousness. It appears likely that consciousness will not be localizable; although it may be highly dependent on specific brain structures (e.g., those that regulate sleep vs wakefulness, etc.), it may well depend on the intact functioning of many interacting parts of the brain. Exactly why or how consciousness arises from these interactions is not at all understood.

What Is the Basis for the Unique Cognitive Capacities of the Human Brain, Relative to that of Other, Simpler Organisms?

The issue of what sets humans apart from other organisms remains one of the central unresolved questions. The similarity of the human genome to that of closely related species can be taken in different ways. It can suggest to some that a very small number of specific faculties have been added that differentiate the human from, say, the chimpanzee; or it could suggest that rather than new faculties, the human brain really differs only in the expansion and extension of structures already present to a degree in other organisms. The idea that the highest cognitive functions are emergent functions rather than localizable or

locally encoded in genes remains an attractive, though elusive possibility.

The Future of Cognitive Neuroscience

Nobel laureate Eric Kandel has suggested that cognitive neuroscience will increasingly assume center stage in the neurosciences in the twenty-first century, and it has begun to make dramatic inroads into the field of cognitive psychology, where many leading investigators have redirected their research to exploit ideas and methods from neuroscience. Future research in cognitive neuroscience will address the general issues raised above as well as many other topics. What makes the future of the field so exciting is the prospect of further development of a number of important contributing methodologies. Breakthroughs in functional brain imaging and other related methods are likely to provide far greater spatial and temporal resolution of brain activity. Another, very important area of methodological advance is the ability to create genetically altered brains especially in small mammals and invertebrates, and thereby to explore the consequences of these alterations for function (*see* Genetic Approaches to Memory). These methods have already reached the point where it is possible to allow an organism to develop normally, and then induce a region-specific gene knockout, thereby providing the opportunity to investigate, for example, the effect of the alternation of synaptic plasticity in a specific part of the brain. Breakthroughs should be expected in many other areas of cognitive neuroscience as well, including neuronal recording, functional imaging, and computational modeling approaches. Together, these methods will lead to a deeper understanding of how the highest capabilities of the human mind arise from the underlying physical and chemical processes in the brain.

Abstract

Modern cognitive psychology began in the late 1950s, when American and British psychologists rejected behaviorism and adopted a model of the mind based on the computer. The overthrow of behaviorism came not so much from ideas within psychology as from three research approaches external to the field, including: (1) communications research including information theory; (2) the computer modeling approach, particularly the work of Newell and Simon; and (3) the generative linguistics approach, particularly the work of Chomsky. The merging of these approaches with substantive psychology led to the information-processing approach to cognition, which emphasized the representations and processes needed to give rise to mental activities ranging from pattern recognition, attention, categorization, memory, reasoning, decision making, problem solving, and language.

Since the beginning of experimental psychology in the nineteenth century, there had been interest in the study of higher mental processes. But something discontinuous happened in the late 1950s, something so dramatic that it is now referred to as the 'cognitive revolution,' and the view of mental processes that it spawned is called 'cognitive psychology.' What happened was that American psychologists rejected behaviorism and adopted a model of mind based on the computer. The brief history that follows (adapted in part from Hilgard (1987) and Kessel and Bevan (1985)) chronicles mainstream cognitive psychology from the onset of the cognitive revolution to the beginning of the twenty-first century.

Beginnings

From roughly the 1920s through the 1950s, American psychology was dominated by behaviorism. Behaviorism was concerned primarily with the learning of associations, particularly in nonhuman species, and it constrained theorizing to stimulus-response notions. The overthrow of behaviorism came not so much from ideas within psychology as from three research approaches external to the field.

Communications Research and the Information-Processing Approach

During World War II, new concepts and theories were developed about signal processing and communication, and these ideas had a profound impact on psychologists active during the war years. One important work was Shannon's (1948) paper about *Information Theory*. It proposed that information was communicated by sending a signal through a sequence of stages or transformations. This suggested that human perception and memory might be conceptualized in a similar way: sensory information enters the receptors, then is fed into perceptual analyzers, whose outputs in turn are input to memory systems. This was the start of the 'information-processing' approach – the idea that cognition could be understood as a flow of information within the organism, an idea that continues to dominate cognitive psychology.

Perhaps the first major theoretical effort in information-processing psychology was Donald Broad-bent's *Perception and Communication* (Broadbent, 1958). According to Broadbent's model, information output from the perceptual system encountered a filter, which passed only information to which people were attending. Although this notion of an all-or-none filter would prove too strong (Treisman, 1960), it offered a mechanistic account of selective attention, a concept that had been banished during behaviorism. Information that passed Broadbent's filter then moved on to a 'limited capacity decision channel,' a system that has some of the properties of short-term memory, and from there on to long-term memory. This last part of Broadbent's model – the transfer of information from short- to long-term memory – became the salient point of the dual-memory models developed in the 1970s.

Another aspect of Information theory that attracted psychologist's interest was a quantitative measure of information in terms of 'bits' (roughly, the logarithm to the base two of the number of possible alternatives). In a still widely cited paper, George Miller (1956) showed that the limits of short-term memory had little to do with bits. But along the way, Miller's and others' interest in the technical aspects of information theory and related work had fostered mathematical psychology, a subfield that was being fueled by other sources as well (e.g., Estes and Burke, 1953; Luce, 1959; Garner, 1962). Over the years, mathematical psychology has frequently joined forces with the information-processing approach to provide precise claims about memory, attention, and related processes.

The Computer Modeling Approach

Technical developments during World War II also led to the development of digital computers. Questions soon arose about the comparability of computer and human intelligence (Turing, 1950). By 1957, Alan Newell, J.C. Shaw, and Herb Simon had designed a computer program that could solve difficult logic problems, a domain previously thought to be the unique province of humans. Newell and Simon soon followed with programs that displayed general problem-solving skills

much like those of humans, and argued that these programs offered detailed models of human problem solving (a classic summary is contained in Newell and Simon (1972)). This work would also help establish the field of artificial intelligence (AI).

Early on, cross-talk developed between the computer modeling and information-processing approaches, which crystallized in the 1960 book *Plans and the Structure of Behavior* (Miller et al., 1960). The book showed that information-processing psychology could use the theoretical language of computer modeling even if it did not actually lead to computer programs. With the 'bit' having failed as a psychological unit, information processing badly needed a rigorous but rich means to represent psychological information (without such representations, what exactly was being processed in the information-processing approach?). Computer modeling supplied powerful ideas about representations (as data structures), as well as about processes that operate on these structures. The resultant idea of human information processing as sequences of computational processes operating on mental representations remains the cornerstone of modern cognitive psychology (see, e.g., Fodor, 1975).

The Generative Linguistics Approach

A third external influence that lead to the rise of modern cognitive psychology was the development of generative grammar in linguistics by Noam Chomsky. Two of Chomsky's publications in the late 1950s had a profound effect on the nascent cognitive psychology. The first was his 1957 book *Syntactic Structures* (Chomsky, 1957). It focused on the mental structures needed to represent the kind of linguistic knowledge that any competent speaker of a language must have. Chomsky argued that associations per se, and even phrase structure grammars, could not fully represent our knowledge of syntax (how words are organized into phrases and sentences). What had to be added was a component capable of transforming one syntactic structure into another. These proposals about transformational grammar would change the intellectual landscape of linguistics, and usher in a new psycholinguistics.

Chomsky's second publication (1959) was a review of *Verbal Behavior*, a book about language learning by the then most respected behaviorist alive, B.F. Skinner (Skinner, 1957). Chomsky's review is arguably one of the most significant documents in the history of cognitive psychology. It aimed not merely to devastate Skinner's proposals about language, but to undermine behaviorism as a serious scientific approach to psychology. To some extent, it succeeded on both counts.

An Approach Intrinsic to Psychology

At least one source of modern cognitive psychology came from within the field. This approach had its roots in Gestalt psychology, and maintained its focus on the higher mental processes. A signal event in this tradition was the 1956 book *A Study of Thinking*, by Bruner, Goodnow, and Austin (Bruner et al., 1956). The work investigated how people learn new concepts and categories, and it emphasized strategies of learning rather than just associative relations. The proposals fit perfectly with the information-processing approach – indeed, they were information-processing proposals – and offered still another reason to break from behaviorism.

By the early 1960s all was in place. Behaviorism was on the wane in academic departments all over America (it had never really taken strong root in Europe). Psychologists interested in the information-processing approach were moving into academia, and Harvard University went so far as to establish a Center for Cognitive Studies directed by Jerome Bruner and George Miller. The new view in psychology was information processing. It likened mind to a computer, and emphasized the representations and processes needed to give rise to activities ranging from pattern recognition, attention, categorization, memory, reasoning, decision making, problem solving, and language.

The Growth of Cognitive Psychology

The 1960s brought progress in many of the above-mentioned topic areas, some of which are highlighted below.

Pattern Recognition

One of the first areas to benefit from the cognitive revolution was pattern recognition, the study of how people perceive and recognize objects. The cognitive approach provided a general two-stage view of object recognition: (1) describing the input object in terms of relatively primitive features (e.g., 'it has two diagonal lines and one horizontal line connecting them'); and (2) matching this object description to stored object descriptions in visual memory, and selecting the best match as the identity of the input object ('this description best matches the letter A'). This two-stage view was not entirely new to psychology, but expressing it in information-processing terms allowed one to connect empirical studies of object perception to computer models of the process. The psychologist Ulrich Neisser (1964) used a computer model of pattern recognition (Selfridge, 1959) to direct his empirical studies and provided dramatic evidence that an object could be matched to multiple visual memories in parallel.

Other research indicated that the processing underlying object perception could persist after the stimulus was removed. For this to happen, there had to be a visual memory of the stimulus. Evidence for such an 'iconic' memory was supplied by Sperling in classic experiments in 1960 (Sperling, 1960). Evidence for a comparable brief auditory memory was soon provided as well (e.g., Crowder and Morton, 1969). Much of the work on object recognition and sensory memories was integrated in Neisser's influential 1967 book *Cognitive Psychology* (Neisser, 1967). The book served as the first comprehensive statement of existing research in cognitive psychology, and it gave the new field its name.

Memory Models and Findings

Broadbent's model of attention and memory stimulated the formulation of rival models in the 1960s. These models assumed that short-term memory (STM) and long-term

memory (LTM) were qualitatively different structures, with information first entering STM and then being transferred to LTM (e.g., Waugh and Norman, 1965). The Atkinson and Shiffrin (1968) model proved particularly influential. With its emphases on information flowing between memory stores, control processes regulating that flow, and mathematical descriptions of these processes, the model was a quintessential example of the information-processing approach. The model was related to various findings about memory. For example, when people have to recall a long list of words they do best on the first words presented, a 'primacy' effect, and on the last few words presented, a 'recency' effect. Various experiments indicated that the recency effect reflected retrieval from STM, whereas the primacy effect reflected enhanced retrieval from LTM due to greater rehearsal for the first items presented (e.g., Murdock, 1962; Glanzer and Cunitz, 1966). At the time these results were seen as very supportive of dual-memory models (although alternative interpretations would soon be proposed – particularly by Craik and Lockhart, 1972).

Progress during this period also involved empirically determining the characteristics of encoding, storage, and retrieval processes in STM and LTM. The results indicated that verbal material was encoded and stored in a phonologic code for STM, but a more meaning-based code for LTM (Conrad, 1964; Kintsch and Buschke, 1969). Other classic studies demonstrated that forgetting in STM reflected a loss of information from storage due to either decay or interference (e.g., Wickelgren, 1965), whereas some apparent losses of information in LTM often reflected a temporary failure in retrieval (Tulving and Pearlstone, 1966). To a large extent, these findings have held up during over 30 years of research, although many of the findings would now be seen as more limited in scope (e.g., the findings about STM are now seen as reflecting only one component of working memory, e.g., Baddeley (1986), and the findings about LTM are seen as characterizing only one of several LTM systems, e.g., Schacter (1987)).

One of the most important innovations of 1960s research was the emphasis on reaction time as a dependent measure. Because the focus was on the flow of information, it made sense to characterize various processes by their temporal extent. In a seminal paper in 1966, Saul Sternberg reported (Sternberg, 1966) that the time to retrieve an item from STM increased linearly with the number of items in store, suggesting that retrieval was based on a rapid scan of STM. Sternberg (1969) gave latency measures another boost when he developed the 'additive factors' method, which, given assumptions about serial processing, allowed one to attribute changes in reaction times to specific processing stages involved in the task (e.g., a decrease in the perceptibility of information affected the encoding of information into STM but not its storage and retrieval). These advances in 'mental chronometry' quickly spread to areas other than memory (e.g., Fitts and Posner, 1967; see also Schneider and Shiffrin, 1977).

The New Psycholinguistics

Beginning in the early 1960s there was great interest in determining the psychological reality of Chomsky's theories of language (these theories had been formulated with ideal listeners and speakers in mind). Some of these linguistically inspired experiments presented sentences in perception and memory paradigms, and showed that sentences deemed more syntactically complex by transformational grammar were harder to perceive or store (Miller, 1962). Subtler experiments tried to show that syntactic units, like phrases, functioned as units in perception, STM, and LTM (Fodor et al. (1974) is the classic review). While many of these results are no longer seen as critical, this research effort created a new subfield of cognitive psychology, a psycholinguistics that demanded sophistication in modern linguistic theory.

Not all psycholinguistic studies focused on syntax. Some dealt with semantics, particularly the representation of the meanings of words, and a few of these studies made use of the newly developed mental chronometry. One experiment that proved seminal was reported by Collins and Quillian (1969). Articipants were asked simple questions about the meaning of a word, such as 'Is a robin a bird,' and 'Is a robin an animal?'; the greater the categorical difference between the two terms in a question, the longer it took to answer. These results were taken to support a model of semantic knowledge in which meanings were organized in a hierarchical network, e.g., the concept 'robin' is directly connected to the concept 'bird,' which in turn is directly connected to the concept 'animal,' and information can flow from 'robin' to 'animal' only by going through 'bird' (see the top of **Figure 1**). Models like this were to proliferate in the next stage of cognitive psychology.

The Rise of Cognitive Science

Memory and Language

Early in the 1970s the fields of memory and language began to intersect. In 1973 John Anderson and Gordon Bower published *Human Associative Memory* (Anderson and Bower, 1973), which presented a model of memory for linguistic materials. The model combined information processing with recent developments in linguistics and AI, thereby linking the three major research directions that led to the cognitive revolution. The model used networks similar to that considered above to represent semantic knowledge, and used memory-search processes to interrogate these networks (see the middle of **Figure 1**). The Anderson and Bower book was quickly followed by other large-scale theoretical efforts that combined information processing, modern linguistics, and computer models. These efforts included Kintsch (1974), which focused on memory for paragraphs rather than sentences, and Norman et al. (1975), Anderson (1976), and Schank and Abelson (1977), which took a more computer-science perspective and focused on stories and other large linguistic units.

As psychologists became aware of related developments in linguistics and AI, so researchers in the latter disciplines become aware of pertinent work in psychology. Thus evolved the interdisciplinary movement called 'cognitive science.' In addition to psychology, AI, and linguistics, the fields of cultural anthropology and philosophy of mind also became involved. The movement eventuated in numerous interdisciplinary

Figure 1 (a) Part of a Collins, A.M., Quillian, R.M., 1969. Retrieval time from semantic memory. Journal of Verbal Learning and Verbal Behavior 8, 240–247 semantic network. Circles designate concepts and lines (arrows) between circles designate relations between concepts. There are two kinds of relations: subset-superset ('Robin is a bird') and property (e.g., 'Robins can fly'). The network is strictly hierarchical, as properties are stored only at the highest level at which they apply. (b) Part of an Anderson, J.R., Bower, G.H., 1973. Human Associative Memory. Winston, Washington, DC propositional network. Circles represent concepts and lines between them labeled relations. All propositions have a subject-predicate structure, and the network is not strictly hierarchical. (c) Part of a simplified connectionist network. Circles represent concepts, or parts of concepts, lines with arrowheads depict excitatory connections, and lines with filled circles designate inhibitory connections; typically numbers are put on the lines indicate the strength of the connections. The network is not strictly hierarchical, and is more interconnected than the preceding networks.

collaborations (e.g., Rumelhart et al., 1986), as well as in individual psychologists becoming more interdisciplinary.

Representational Issues

In the 1970s and early 1980s, cognitive science was much concerned with issues about mental representations. Whereas the memory-for-language models described earlier had assumed representations that were language-like, or propositional, other researchers argued that representations could also be imaginal, like a visual image. Shepard and Cooper (1972) provided evidence that people could mentally rotate their representations of objects, and Kosslyn (1980) surveyed numerous phenomena that further implicated visual imagery. In keeping with the interdisciplinariness of cognitive science, AI researchers and philosophers entered the debate about propositional versus imaginal representations (e.g., Block, 1981; Pylyshyn, 1981). In addition to questions about the modality of representations, there were concerns about the structure of representations. While it had long been assumed that

propositional representations of objects were like definitions, researchers now proposed the representations were *prototypes* of the objects, fitting some examples better than others (Tversky, 1977; Mervis and Rosch, 1981; Smith and Medin, 1981). Again the issues sparked interest in disciplines other than psychology (e.g., Lakoff, 1987).

The cognitive science movement affected most areas of cognitive psychology, ranging from object recognition (Marr, 1982) to reasoning (e.g., Johnson-Laird, 1983) to expertise in problem solving (e.g., Chase and Simon, 1973). The movement continues to be influential and increasingly focuses on computational models of cognition. What has changed since its inception in the 1970s is the kind of computational model in favor.

Newer Directions: Connectionism and Cognitive Neuroscience

Connectionist Modeling

The computer models that dominated cognitive psychology from its inception used complex symbols as representations, and processed these representations in a rule-based fashion (e.g., in a model of object recognition, the representation for a frog might consist of a conjunction of complex properties, and the rule for recognition might look something like 'If it's green, small, and croaks, it's a frog'). Starting in the early 1980s, an alternative kind of cognitive model started to attract interest, namely 'connectionist' (or 'parallel distributed processing') models. These proposals have the form of neural networks, consisting of nodes (representations) that are densely interconnected, with the connections varying in strength (see the bottom of **Figure 1**).

In 1981 Hinton and Anderson published a book surveying then existent connectionist models (Hinton and Anderson, 1981), and in the same year McClelland and Rumelhart (1981) presented a connectionist model of word recognition that explained a wide variety of experimental results. The floodgates had been opened, and connectionist models of perception, memory, and language proliferated, to the point where they now dominate computational approaches to cognition. Why the great appeal? One frequently cited reason is *neurological plausibility*: the models are clearly closer to brain function than are traditional rule-based models. A second reason is that connectionist models permit *parallel constraint satisfaction*: different sources of activation can converge simultaneously on the same representations or response. A third reason is that connectionist models manifest *graceful degradation*: when the model is damaged, performance degrades slowly, much as is found in human neurological disorders (Rumelhart et al., 1986).

From a historical viewpoint, there is an ironic aspect about the ascendancy of connectionist models. Such models return to the pure associationism that characterized behaviorism. While connectionist models hardly fit with all behaviorist dictums – their representations are not restricted to stimuli and responses, and they routinely assume massively parallel processing – still their reliance on associations runs counter to Chomsky's arguments that sheer associationism cannot explain language (Chomsky, 1957, 1959). This issue has formed part of the basis for critiques of connectionist models (e.g., Fodor and Pylyshyn, 1988). Newell (1990), one of the founders of traditional computational models, suggested a plausible resolution: lower-level cognitive processes like object recognition may be well modeled by connectionist models, but higher-level cognitive processes like reasoning and language may require traditional symbolic modeling.

Cognitive Neuroscience

The other major new direction in cognitive psychology is the growing interest in the neural bases of cognition, a movement referred to as 'cognitive neuroscience.' There had been little interest in biological work in the research that brought about the cognitive revolution. That early work was as much concerned with fighting behaviorism as it was with advancing cognitive psychology, and consequently much of the research focused on higher-level processes and was completely removed from anything going on in the neurobiology of its day. Subsequent generations of cognitive psychologists solidified their commitments to a purely cognitive level of analyses, by arguing that the distinction between cognitive and neural levels of analyses was analogous to that between computer software and hardware, and that cognitive psychology (and cognitive science) was concerned primarily with the software. Since the early 1990s, views about the importance of neural analyses have changed dramatically. There is a growing consensus that the standard information-processing analyses of cognition can be substantially enlightened by knowing how cognition is implemented in the brain.

While many factors may have been responsible for the change in view, three will be mentioned here. First, the rise of connectionist models that were loosely inspired by brain function had the side effect of increasing interest in what was known in detail about brain function. Indeed, these two recent movements have become increasingly intertwined as connectionist models have increasingly incorporated findings from cognitive neuroscience. Second, in the 1970s and 1980s there were breakthroughs in systems-level neuro-science that had implications for mainstream cognitive psychology. As one example, research with neurological patients as well as with nonhuman species established that structures in the medial temporal lobe were essential for the formation of memories that could serve as the basis for recall ('explicit memory'), but not for other kinds of 'implicit memories' (e.g., Schacter, 1987; Squire, 1992). As another example, research with nonhuman primates showed that two distinct systems were involved in the early stages of visual perception: a 'where' system that is responsible for spatial localization, and a 'what' system that is responsible for recognition of the object (e.g., Ungerleider and Mishkin, 1982). Both of these discoveries had major implications for the cognitive level of analyses, e.g., computational models of object recognition or memory would do well to divide the labor into separate subsystems.

The third factor responsible for the rise of cognitive neuroscience is methodological: the development of neuroimaging techniques that produce maps of neural activity while the brain is performing some cognitive task. One major technique is positron emission tomography (PET). In 1988,

Michael Posner, Marcus Raichle, and colleagues used PET in a groundbreaking experiment to localize neurally different subprocesses of reading – PET images obtained while participants looked at words showed activated regions in the posterior temporal cortex; images obtained while participants read the words revealed additional regions activated in the motor cortex; and images obtained while participants generated constrained associations to the words revealed still additional regions in frontal areas (Posner et al., 1988). PET analyses of object recognition, memory, and language soon followed. A more recent technique is functional magnetic resonance imaging. It is now being used to study virtually every domain of human cognition.

Conclusion

This article has given short shrift to important contributions that tend to fall off the mainstream of cognitive psychology. One such case is the work done by Dan Kahneman and Amos Tversky (e.g., Kahneman and Tversky, 1973; Tversky and Kahneman, 1983) on the use of heuristics in decision making, which can result in deviations from rational behavior. Another example is the cognitively inspired study of memory and language deficits in neurological patients (Shallice (1988) provides a review). There are other cases like these which deserve a prominent place in a fuller history of cognitive psychology.

Cognitive Styles and Learning Styles

Stephen G Rayner, Newman University, Birmingham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The psychological construct of style in personality, cognition, and learning is explained in this article. The development of a styles theory is interpreted as the evolution of a generic concept of individuality and its status as an individual difference in cognition and learning. The emergence of popular applications of learning styles as well as a wave of critical revisionism and new directions in researching style differences is related to this development. An application of style differences for lifelong learning in both education and workplace are then considered, including implications for further study of differential psychology, pedagogy, training, and the nature of an individual's personal approach to learning (style).

Style Differences and Individuality: Cognition, Behavior, and Affect

The commonsense idea of style is one of the distinctive and personal signatures or hallmarks woven into an individual's performance (Rayner, 2000, 2001). Less clear, however, is use of the term 'style' when applied in personal or differential psychology, involving aspects of affect, behavior, cognition, intelligence, personality, self-perception, and social identity (Rayner and Peterson, 2009; Peterson et al., 2009). The implications of style differences for understanding how affect, behavior, and cognition in the person combine to form individuality is reflected in a traditional contribution to psychometric assessment and factor analytic research across three key areas of human performance: first, profiling individual differences in workplace and educational settings (Messick, 1976; Jonassen and Grabowski, 1993); second, exploiting the presence and effect of style features as variables in learning and teaching (Kolb, 1976; Entwistle, 1981; Schmeck, 1988); and third, reasserting the conceptual basis of the style construct in personal and social behavior (Witkin et al., 1962; Sternberg, 1996; Rayner and Riding, 1997; Peterson et al., 2009).

An aim in the research over time has arguably been to describe a holistic but valid and reliably consistent theory of style, distinct from and separate to other individual differences (constructs) such as personality, intelligence, identity, and gender (Miller, 1987; Curry, 1987; Rayner and Riding, 1997). In more recent work (Rayner and Cools, 2011; Zhang et al., 2012), an account is made reexamining the basis of styles as traits, states, identities, and intellectual processes. Renewed interest in style research has also coincided with calls for developing alternative ways of researching style combining new forms of research methodology and epistemology (Rayner and Peterson, 2009; Cools and Rayner, 2011; Rayner, 2011).

The Style Construct in the Psychology of Education

The exact structure and nature of the style construct remains contested (Messick, 1976, 1994, 1996; Ritter, 2007). Similarly, the effect size associated with various measurements of a style factor in educational research (variously described as cognitive, thinking, learning, or intellectual styles) remains disappointingly small when applied to contexts of learning and work-related behavior (Kavale and Forness, 1987; Coffield et al., 2004; Pashler et al., 2008; Peterson et al., 2009). This is an important issue to which we will again return later in this discussion. The utility and integrity of style as a construct, however, is clearly reliant upon a well-established theory, which is both coherent and consistent in terms of conceptual rigor, distinctive validity, independence as a construct, and epistemic robustness.

The following recategorization of cognitive styles begins by distinguishing research in the mid part of the twentieth century, as the production of a styles construct associated with: (1) personality-based styles reflecting type and trait as key indicators of an individual's innate behavior across different contexts of performance; (2) more stable cognition-centered structures and/or dimensions of a person's cognitive style associated with traitlike differences in an individual's tendency to think, feel, or act; (3) less stable cognitive processes linked to the ways in which cognitive controls, strategies, and processes combine in an individual's approach to demand or task in a range of contexts; and (4) preferences for learning and thinking affected by modality, cognitive processes, and learning experiences, while engaged in completing an assigned activity. The first is related to constructs associated with 'personality-based styles,' the second to 'cognition-centered styles,' the third learning strategies, learning patterns, and an orientation to learning, and the fourth, generic 'learning-based styles.'

The fourth part of this style recategorization which involves the identification and development of 'learning styles' reflects a refocused interest upon the question of 'person-environment fit,' and so is associated with a widening range of executive functions in the psychology of the individual when engaged with a task-related performance. This includes intellectual styles related to the following: multiple intelligences or abilities, problem solving, creativity, intuition, decision-making, and a wider range of style-based learning behaviors integrating learning styles with learning strategies as part of an effort to create a framework for applying 'holistic' style profiles (for example, combining personal learning style, learning preferences, experiential learning, learning motivation, and forms of accelerated, extended, or enhanced learning).

Personality Styles – Types of Individuality

An early influence in the development of style as type may be linked to the work of Jung's typology of personality constructs and 'psychoanalytic ego psychology' (Jung, 1923). The most influential style model emerging from this paradigm was the Myers–Briggs Type Indicator (Myers, 1978; Myers-Briggs, 1980). This test is generally recognized as a measure of personal style but conversely is described as a personality test (Isaksen et al., 2003; Hough and Ogilvie, 2005). The Myers–Briggs Type Indicator is purported to have become one of the most widely used measures of psychological types in business and public sector organizations. Few studies, however, have been published examining its efficacy (Kelley, 2005).

A separate development to both the theorizing and measuring aspects of personality as individual *preferences* was constructed by Holland (Holland, 1973, 1985; Gottfredson and Holland, 1996), focusing upon individual career choices or planning. Holland's theory is based upon the idea of defining personality types in terms of occupational preferences: these include Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (Holland, 1973). Much of this 'type' theory reflects a similar set of ideas about preferences and trait underpinning the application of a range of style theories including the fundamental idea of the 'matching hypothesis,' which supposes that a deliberate style-led matching of different personality types with task, mode of work, grouping, and context can enhance performance.

According to Sternberg (1997), intellectual styles function at the interface between ability and personality. The psychological structure of style posited in this way describes a relatively stable but complex interactive system that embodies psychological controls, processes, and states but also reflects an executive function regulating personal, physiological, and sociological aspects of the individual's mind at work. For some psychologists, it is self-evident that style and personality represent very similar explanations of individuality and simply are manifestations of one and the same construct (see Messick, 1994; Chamorro-Premuzic and Furnham, 2006; Furnham et al., 2008). It is argued here, however, that the structure and function of the style construct is closely implicated with rather than an aspect of personality. It contributes to a holistic structure (or model) shaping as well as sustaining and reflecting an individual's psychology, including structural forms of their personality, cognition, and behavior (Riding and Rayner, 1998).

Cognitive Styles – Types of Process in Human Cognition

The following section provides a summary of the work related to styles defined as internal control processes and strategies in human cognition. A useful account of the historical development of this work can be found in Kozhevnikov (2007). This is further complemented by analytic reviews offered by Grigerenko and Sternberg (1995), Rayner and Riding (1997), and Zhang and Sternberg (2005). The best introduction to the original styles experiments and source for the construct can be found in Messick (1976).

Perceptual Differentiation

Witkin and coworkers produced seminal work over a period of more than 50 years – originating in an interest with the 'regularities' of information processing, derived from the German gestalt school of perceptual psychology, and which led to an early development of the 'style construct' of 'Field Dependence-Independence' (FDI). The practical issues related to flying aircraft through dense cloud formation were the original spur to investigating what and how individual intradifferences were found to influence crucial variations in pilots maintaining course and control in their aircraft. Individuals, when reorienting an object relative to the vertical, were found to rely upon the surrounding 'field' or 'context' to a greater or lesser extent. This was subsequently found to correlate with competence in disembedding shapes from a perceptual field, and experimental participants were found to either rely heavily on the field for orientation or shape discrimination (field-dependent) or rely little or not at all (field-independent).

The assessment tools developed as part of this research included an original rod and frame tilting chair experiment and then the 'pencil and paper' embedded figures test. While a great deal of critique was subsequently leveled at the FDI theory for confounding abilities and style, Witkin and Ash (1948) extrapolated a comprehensive theory of psychological differentiation to explain how it affected a wide range of human performance across a breadth of social and personal contexts.

Cognitive Controls and Cognitive Processes

Psychologists interested in cognitive control processes and structure produced a second alternative approach to theorizing intradifferences in personality and style. Early experimental work at the Messinger Clinic in the USA developed notions of ego adaptation to the environment in the individual (Gardner, 1953; Gardner et al., 1959). This led to further experimental research hypothesizing style as a key factor in facilitating stable responses (styles) in the individual to the situation, producing patterns of response and function in thinking and behavior (Messick, 1976).

The program completed by these coworkers over more than 20 years produced a series of 'styles' (to function rather like a set of cogs and balances in the cognitive machinery of the mind), usually comprising a bipolar structure and implicated in a wide range of adaptive responses to differing demands in the experimental context. These included, for example, stimuli differentiation ('levelers' and 'sharpeners') identified by Klein (1958), which subsequently developed to include differences in other forms of cognitive scanning, categorization, conceptual articulation, and degree of cognitive control (Gardner et al., 1959; Messick and Fritzky, 1963). A third focus provided by Kagan and coworkers investigating types and levels of response to cognitive uncertainty typically recorded during problem-solving task completion. This latter work identified two types of typical response along a continuum of conceptual tempo, from the impulsive to reflective (Kagan, 1966). It led in turn to the claim for a unique style dimension identified using the Matching Familiar Figures Test (Kagan, 1965).

Mental Imagery, Memory, and Thinking

Similar research around the same time involved exploring individual differences in mental representation and visual information processing: this included looking at visual and/or verbal ways of representing information in thought, as well as visual or imaginal processes used in dealing with new information. Research led by Pask (1972, 1976) on style and information processing introduced the idea of serial or holistic processing. This research identified how the individual would split and separate (serialist type) or group and synthesize (holist type) new information when dealing with a problem-solving task (Pask and Scott, 1972).

At the same time, other work investigating mental imagery revealed how some people have a predominantly verbal way of representing information in thought, while others are more 'visual' or 'imaginal.' Paivio (1971) further developed this theory with a dual coding measurement of mental imagery. Further research completed by Richardson (1977) using the Verbalizer–Visualizer Questionnaire revealed habitual methods of visual thinking. Most recent work investigating the way in which these style dimensions may function has been completed by Kozhevnikov et al. (2005), and secondly, Miller et al. (2012), providing new neurological evidence of style-related mental activity, elicited from the use of functional magnetic resonance imaging (fMRI) and data analysis employing *t*-statistic mapping of brain function.

Riding and Taylor (1976) initially identified, as fundamental to the style construct, a verbal-imagery dimension of cognitive style. This led to the construction of the 'cognitive styles assessment' (CSA), used to support further research in developing an integrated theory of cognitive style (Riding, 1991). The model of style presented subsequently by Riding and Rayner (1998) described an orthogonal arrangement of two fundamental but independent dimensions of cognitive style: the verbal-visualizer style continuum and the wholist–analytic style continuum. These dimensions are assessed by the CSA, a computerized test locating a respondent on each of the wholist–analytic and verbal-imagery dimensions of a cognitive style (Riding, 1991).

Research into Executive Functioning and Differences in Thinking

A widening field of research that was interested in how executive functioning and individual differences in thinking and action influence key aspects of human performance emerged in the latter part of the twentieth century. The work involved many researchers independently constructing new models and measures, thereby adding to a broad and disparate theoretical base, and fueling in turn an increasing number of loosely linked conceptions of style in thinking, learning, and performance.

These various style labels reflecting aspects of cognitive functioning included a model of phenomenological style (Gregorc, 1982); the Adaptor–Innovator cognitive style of decision-making (Kirton, 1994); an intuitive–analytic cognitive style of problem solving (Hayes and Allinson, 1998); cognitive styles analysis focusing upon information processing/mental representation (see Riding, 1991; Riding and Rayner, 1998); and a cognitive style of creativity (Kaufmann, 1989). Another more elaborate model of mental self-government presented by Sternberg (1996, 1997), represented a theory of style derived from notions of a holistic regulation in the mind, integrating constructs of intelligence, abilities, and self-government. According to this theory, individual differences in styles or mental processes can be understood in terms of function, form, level, scope, and leaning, which impact upon thinking and learning.

The final word on the importance of this phase of research development belongs to Kozhevnikov (2007). She explains that its significance principally lies with an attempt to both expand and clarify the mechanisms of cognitive styles in the context of an information processing approach. She argues that there is sufficient evidence to suggest a theoretical basis for the hierarchical classification of cognitive styles according to the level of information processing in which the individual is engaged (from simple perceptual decisions to complex problem solving).

Learning Styles: Personal Differences in Approach and Performance

The development of learning styles research was preceded by work on the assessment of the learner, learning, and teaching. This work, epitomized by the activity of the American National Association of Secondary School Principals (NASSP) task force looking at learning styles (Keefe, 1985), triggered a wave of new models of style, with a great many populist versions, and more recently accessible from the Internet. The result was a proliferation in the range of user-sourced tools of assessment, hybrid forms of style theory, and many commercial packages advocating all in one approaches to personalizing educational intervention. This development was further reinforced by popular interpretations of advances in neuroscience, producing different versions of learning styles applied to teaching and learning in the classroom (Geake, 2008).

In spite of this popularizing trend, several developing theories explaining approaches to individual differences in learning reflected cautious and well-established applied research. This section includes a summary of some key theories of learning styles organized into the following four groups: models focusing on experiential learning; models based on orientation to study; models based upon instructional preferences; and models based upon learning skills associated with neuroscience. The latter research in particular reflected attempts to explore respectively and in combination interaction between inter- and intra-differences in learning and the learner when engaged in learning.

Models Focusing on Experiential Learning

Models derived from a theory of experiential learning, of which most influential is the work of Kolb (1976), described learning styles as the individual's preferred method for assimilating information, in an active learning cycle. Kolb constructed a two-dimensional model comprising perception (concrete/abstract thinking) and processing (active/reflective information processing), treating these as fundamental aspects of an experiential learning cycle. The assessment tool used for this learning styles model is the Learning Styles Inventory (LSI)

(Kolb, 1999). Recent research further developing this model in studies of undergraduate MBA courses in the USA is reported by Sharma and Kolb (2011), a new form of related assessment reported by Boyatzis and Mainemelis (2011) and related pedagogic development (Portugal and the UK) reported by Almeida et al. (2011).

Models Based on Orientation to Study

These derived from earlier theories of information processing and learning processes; the most influential has been that of Entwistle (1981), in developing the early work of Pask (1972) to produce a measure called the Approaches to Study Inventory. This paved the way for a good deal of subsequent research exploring how learners construct an approach to learning and how this interacts with motivation (Marton and Saljo, 1976; Vermunt, 1996; Entwistle and Peterson, 2004). The 'approaches to learning' model is widely referred to in University education (Biggs, 2001; Vermunt, 2011), and typically describes ways in which students engage with deep or surface learning, thus reflecting the adoption of one or more orientations to study (meaning, reproducing, achieving, and holistic learning). These choices of approach reflect a series of orientations that are thought to be relatively stable differences in study behavior but remain susceptible to change as patterns of learning.

Models Focusing upon Instructional Preference

These set out to present a comprehensive profile of learning differences in the typical response of an individual to instructional contexts. Learning style (Keefe, 1989) was typically perceived as a multimodal construct and understood to describe a range of emotional and intellectual functioning relating to the learning activity. Examples of this approach included the 'Cognitive Profile,' (Letteri, 1980) and the Learning Styles Profile (Keefe, 1985, 1989). It is, however, more widely associated with the program of teacher education promoted by Rita Dunn – the LSI – developed by Dunn et al. (1989).

The learning style elements identified when using the Dunn and Dunn LSI are self-reported responses eliciting information for modal and learning preferences located in the individual student. These are: *environmental stimulus* (light, temperature); *emotional stimulus* (persistence, motivation); *sociological stimulus* (peers, adults); *physical stimulus* (perceptual strengths, time of day – morning vs. after-noon); and *psychological stimulus* (global-analytic, or impulsive reflective). A comprehensive range of learning and teaching materials has been developed by Dunn over a 30-year period to support a learning styles-based differentiation of curricula and pedagogy across the full range of educational phases. It is summarized in Dunn and Griggs (2003), and further theorized in Dunn and Honigsfeld (2011).

Models Based upon Learning Skills and Neuroscience

A fourth group of learning style labels is focused upon an individual's developing cognitive ability and repertoire of cognitive skills or capacity to learn, together with related behavioral characteristics. These were understood to comprise an individual's learning profile. More recent versions in what has amounted to a populist approach to learning styles include the application of a widely established 'visual, auditory, and kinesthetic (VAK)' sensory-based approach to learning and teaching, combining multiple intelligences theory (Gardner, 1983), and neuro-linguistic theory (O'Connor and McDermott, 1996). Other similar 'practical applications' of neuroscientific research and teacher development also popular during the last decade include 'accelerated learning' (Rose and Nicholl, 1997), 'cognitive enhancement' (Adey et al., 1999), and 'personalized learning' utilizing 'learning power' (Ritchie and Deakin Crick, 2005).

Revisionist Theories and Problematizing the Style Construct

An original interest in researching styles from a practitioner's perspective reflects a concern for enhancing learning and teaching that in essence seeks to help 'teach the hard to reach and reach the hard to teach.' For this to happen, styles theory must offer and secure clearly stated relevance, utility, and worthwhile effects for any intervention in the workplace or classroom. The nature of such take up, however, may arguably need to be much more than only the 'Aptitude-by-Treatment Interactions' (ATI) based experimental research advocated by Pashler et al. (2008), and identified as the evidentiary gold standard required to confirm the status of style research.

Rayner (2001), moreover, has argued that the main purpose and value for importing style theory into the design of pedagogy and curricula is the proper use of profiling and assessment as a tool for formative learning. Rosenfeld and Rosenfeld (2011), reflecting a similar 'practitioner' perspective, also argue a need for paradigm shift from second to third person in research design, and call for research directly involving students as individuals working with their own learning styles. They very deliberately challenge the 'ATI template' and traditional experimental design. Such an approach reflects a concern for more applied, humanistic understanding of style differences, as well as providing evidence of impact on 'value for instruction' and 'pedagogic development.'

There are a few but prominent and far reaching critiques of style published in the past 50 years reflecting a more general dissatisfaction with what is described as an unexpectedly gargantuan, complex, and disparate field of research. These criticisms include, for example, the following: no consensual or coherent field theory and consistent psychometric failings across the field in respect to measures of validity, reliability, and effect sizes produced in empirical research (Coffield et al., 2004; Pashler et al., 2008); an incestuous research tradition practiced in a field almost entirely engaged with self-affirming replication (Coffield et al., 2004); a flawed theory of the psychology of learning (Nixon et al., 2007; Geake, 2008); misplaced approaches to pedagogy, curriculum, and scholarship (Sharp et al., 2008); a shortfall in clearly stated or reliable and coherent accounts of value, relevance, and utility of learning styles in the applied context (Reynolds, 1997; Coffield et al., 2004; Peterson et al., 2009); resultant misplaced and restrictive typing, labeling, and harmful individualized practices when applying styles theory to education, instruction, pedagogy, or the curriculum (Coffield et al., 2004; Ritter, 2007; Sharp et al., 2008); reference to alternative more compelling theories and

explanations of the learning process in social psychology and sociology, which in itself is claimed to offer a better prospect of return for resource in the educational setting (Coffield et al., 2004; Nixon et al., 2007; Ritter, 2007).

The issues of these critiques of style research persist to date and invalidate by association a good deal of rigorous and robust work. Nonetheless, continuing criticism of styles research reflecting a mix of ideological conflicts and perspectival differences has led at times to a rejection of any need for styles research. These disputes, however, are often reflected in writers from opposing research epistemologies articulating differing conceptualizations of efficacy and equity for the educational setting. It is salutary and interesting to note Messick's comment that such intensity of conflict was indeed part of the academic debate over 50 years ago. He commented that critique was often "*… excessively polarized in either supporting or undercutting styles as meaningful constructs. This polarization seems to reflect different stances not just with reference to scientific evidence but also with respect to ideology*" (Messick, 1994: 121). There has not been much change over time with the substance of style critique.

Implications of Styles for Lifelong Learning

The extent to which an awareness of cognitive style or learning styles and the self as a learner is currently considered and managed within the learning context raises key questions for the design of training, instruction, and pedagogy. These suggest in turn a need to consider the following key aspects of education construed as contributing to the idea of lifelong learning.

- *Intellectual styles and metacognition* – involving research looking at how intellectual styles (cognition and learning) interact with an awareness of self as a learner and thinker. An obvious implication of this approach to valuing style as a concept lies with its effect upon influencing motivation, behavior, and attribution governing responses to personal achievement. The recent work of Sadler-Smith (2009, 2012) provides an interesting start to a conceptualization linking intuition styles, motivation, and experience with duplex theory and intellectual styles with metacognition.
- *Style and self-regulation in learning* – involving work linking theories of self-regulation with awareness and perceptions of self as a learner. A great deal of integrating work completed by researchers in the area of self-attribution and/or regulation (Zimmerman, 2008) offer a useful model as well as related work for further developing pedagogic approaches to working with student motivation and approaches to learning (see Rayner, 2011; Vermunt, 2011).
- *Assessment-led learning and curriculum differentiation* – meeting the need to further demonstrate relevance and positive effects of style awareness for instructional design in work around the original interest in the *matching hypothesis* (aligning or contrasting style with task or social context to enhance flexibility in the learner and learning outcome). Indeed many writers seem to regard this aspect of 'style' as the only serious implication of style in education (for example, Pashler et al., 2008, devote most of their criticism for the *meshing hypothesis*). Recent work in several areas of style research has reflected confirmation of flexible approaches to learning styles in application (Dunn and Honigsfeld, 2011; Sharma and Kolb, 2011). Similarly, work looking at curriculum differentiation has produced new integrative approaches drawing upon both a cognition and learning centered theory of styles (Rayner, 2000; Evans and Waring, 2011; Zhang et al., 2012).
- *Personalizing education and learning technologies* – a great deal of research is concerned with developing an understanding and thereby facilitating the design of personalized learning. Mourlas et al. (2009) provide an overview of this area exploring 'pedagogic' aspects of the interaction between the individual and web-based or digital infrastructure and/or architecture, with a view to enhancing ways in which an alignment between cognitive style and demands may enhance learning. This not only embraces remote or mobile-digital learning, but learning and teaching applications of social media, intelligent design of technologies, user interface with digital technology and more widely personalizing computer-mediated learning and teaching.
- *Organizational learning, training & business management* – the intuitive appeal of style differences in both cognition and learning continues to generate research and development in the workplace. The key themes emerging in this area are a consideration of the role of style differences in organizational behavior and human resource development including: selection and person-environment fit, vocational choice and career success; diversity, group processes, and conflict management; intuition and emotion in the workplace; training and development; personal styles' profiling; and career management in global organizations (Armstrong and Cools, 2009; Armstrong et al., 2012; Cools, 2012).
- *Pedagogic differences and professional development* – personal and social differences identified in style research impact directly upon the training and the development of professional expertise in professional practitioners (e.g., teachers, trainers, and educators). Much of the research into this area reflects adherence to one or more models of learning styles (for example, Dunn and Griggs, 2003; Sharma and Kolb, 2011). An interesting development in further developing a holistic theory of style, however, is reflected in the earlier work of Sadler-Smith (1996), Peterson et al. (2010) as well as Evans and Waring (2008, 2011), focusing upon teacher training and the effects of raising self-awareness of cognitive style in the teacher's developing pedagogic practice.

The significance of 'style' as reflected in this range of research for the life cycle is clearly about much more than 'style' simply used as a term that has linguistic or conceptual versatility in describing personal performance. While this common usage of the term clearly denotes a popular as well as intuitive appeal and so clearly reflects a universal value, the import of this discussion is that style as an individual difference marks something much more specific in a range of learning associated with the idea of the person engaged in lifelong learning.

Conclusion: A Matter of Style

Why do style differences matter? Knowing more about how *another* or *I* as an individual(s) tend to think, feel and act in

a learning context provides rich possibilities for new ways of setting up, facilitating and leading to any learning activity. Profiling differences and potentials in human performance affords greater awareness for self-directed learning and participation or efficacy in a project group. It is equally relevant to informing differentiated design in programs of study, pedagogic practices, and formative curricula. A style-based contribution to education is also one way in which consideration may be given to further customizing digital technology in better serving personal and social learning across contexts and community.

These implications for further study in differential or personal psychology (individual differences), pedagogy, training and the better management of an individual's personal approach to learning (style) should finally require a closer focus upon types of epistemology and methodology in research design. Rayner (2011) and Rayner et al. (2012), for instance, have argued the need to deliberately attempt paradigm shift to supplement the traditional styles research agenda, which has been largely located in a positivistic paradigm, and more usually employed as an experimental or survey based design associated with the science of cognitive psychology. Whilst this experimental work remains central to style research (Kozhevnikov, 2007), there is a conjoint need for more pluralistic approaches in the design and use of psychological assessment or theorizing of style in cognition, learning, and management.

Sternberg et al. (2012: 416) on the other hand, in a retrospective comment on the recent past in style research makes an argument for much greater emphasis in renewing a factor analytic mode in style research. He acknowledges an urgent need for 'sorting out the theories of style,' and developing 'better forms of style assessment,' but finally stresses the need to reinforce the psychological status of style research utilizing 'random-assignment studies with control groups.' He comments that *The research that has been conducted has been of variable quality and styles would get more research if they were more rigorously researched*. What is very apparent in this view is a need, as suggested earlier, for new ways of constructing the methodology of assessment or testing to better treat complex models of style differences, as have, for example, more recently been occurring in the field of personality (see Hopwood and Donnellan, 2010).

Finally, and as described by Rayner (2013), concern for validity, efficacy, and utility as key markers in a theoretical revisionism within future research and development for the field of 'style differences' rests upon attempting a paradigmatic step change and establishing new ways of modeling and measuring the style construct. Such an approach requires a reexamining of epistemic issues underpinning both the style construct and, as crucially, careful thought about research methodology and project design. It also more fundamentally means responding with greater clarity and certainty to a question about the epistemological status of a 'style' construct asked by Schmidt (2012).

Schmidt points out that the style construct to date is on the one hand conceptualized as a typology in the sense of Hempel's 'aspects of scientific explanation' and more recently tested by procedures such as Latent Class or Latent Profile Analysis (Hempel, 1962, 1965), and, on the other hand, the more traditional approach to style is one in which a classical psychometric method, using exploratory or confirmatory factor analysis for testing reliability and validity, is applied and then classical multivariate models used to test the specific contribution of style. Schmidt questions, therefore, if style research might usefully benefit from adopting an approach combining both perspectives and thereby following a three-step methodology in mixture modeling (see, Jung and Wickrama, 2007; Vermunt, 2010), and which is implemented in programs like Latent Gold or MPLUS (Asparouhov and Bengt, 2013).

This pertinent suggestion offered by Schmidt merits serious consideration as part of what Rayner (2013) argues is a need for problematizing the style construct as a basis for moving forward in the field, thereby leaving a fourth period of research and development (see, Kozhevnikov, 2007), to enter a fifth wave of style research (Rayner, 2013). In many ways this arguably reflects a need to move 'back to the future' and robustly reconsider the question of construct validity at the heart of Messick's work on psychological testing (Schiffman and Messick, 1963; Messick, 1988), and more widely any factorial interaction between personality, style, and abilities (Messick, 1994, 1996).

In conclusion, using style as a psychological construct can aid organizing and developing teams of practitioners in a wide range of organizational activity. But we do need to know much more and as such clearly reestablish or confirm the validity of key style differences, as well as related models or measures, and further affirm a 'grand theory' (general understanding) of the meaning or implications of style. The key theme for utilizing the style construct is captured perfectly in the popular song, *It is not what you do, it is the way that you do it*. The point is not that content is unimportant, but that being aware and knowing more about 'how I tend to do it' can immeasurably help in 'my doing it better.' A greater understanding and improvement of human performance, as psychological process, social behavior, and educational achievement, is the touchstone for future work in applied research aimed at developing style theory, research, and practice.

Cohabitation: United States

Pamela J Smock, Population Studies Center, Institute for Social Research, Ann Arbor, MI, USA

Abstract

Over the past several decades family patterns have changed markedly in the United States and numerous other countries. Prominent increases in nonmarital cohabitation have been central to this change. It is now the norm for individuals to cohabit, whether or not the cohabitation leads to marriage, and the vast majority of marriages now begin as cohabiting relationships. While cohabitation is now common across most population subgroups, there remain economic and racial ethnic differences in the extent to which cohabitation is tied to marriage. Those with higher incomes and education are more likely to transform their cohabiting relationships into marital ones. Major research issues about cohabitation include understanding the striking increase in its popularity, measurement, the implications of cohabitation for children, and the relationship between premarital cohabitation and marital stability.

Cohabitation: An Overview

Only a few decades ago, marriage was the main form of intimate coresidential partnership for heterosexual couples. Beginning in the 1970s, in many Western countries including the United States, couples began living together outside of marriage. Since that time, family demographers and other scholars have been tracking the continued rise in cohabitation and attempting to assess its consequences (Smock, 2000). While this article focuses on the United States, many of the trends and patterns discussed here pertain to other Western contexts.

While marriage remains popular and the vast majority of people express the desire to marry someday, it is no longer the case that marriage is the dominant family form. One indication of this is that cohabitation is not only a step toward marriage. While many cohabiting couples do go on to marry, most others break up within a few years, while a select few remain cohabiting for a significant number of years. Moreover, many cohabiting families include children, either by virtue of a child being born to a cohabiting couple or via a type of 'stepfamily' arrangement in which one parent, usually the mother, begins a cohabiting relationship.

Trends

What was once uncommon has now become the experience of the majority. Currently, there are over 7.8 million heterosexual unmarried couples living together unmarried in the United States, more than twice the number in 2000 (U.S. Bureau of the Census, 2012). One way to get a sense of the trend is to examine the percentages of marriages that begin as cohabiting unions. Four decades ago (1965–74) only 10% of marriages were preceded by cohabitation. This has increased to about two-thirds for couples marrying recently. Marrying without living together is thus now a much less common route to marriage, characterizing only one-third of marriages. In other words, while cohabitation has become increasingly separate from marriage in recent decades, the route to marriage increasingly includes cohabitation. An alternative way to understand the trend is the proportion of first coresidential unions that are cohabitations rather than marriages. About one-half of women ages 15–44 experienced cohabitation as their first union in 2006–10; this is substantially higher than in 1995 when that percentage was 34% (Copen et al., 2013).

Family scholars also use measures of whether an individual has ever cohabited to understand trends in cohabitation. For example, recent surveys indicate that among women ages 30–34, 70% report having ever cohabited compared to just 20% in 1987 (Manning, 2010). In addition, while the likelihood of remarriage after divorce has declined in recent decades, cohabitation appears to be replacing remarriage to some extent. In the 1970s, 24% of women cohabited after divorce. This fraction rose to nearly 50% by the early 2000s (Zeng et al., 2012). It is also important to note that cohabitation is quite common among very young adults, with about half having lived in a cohabiting relationship by the time they reach age 25 (Payne, 2011).

Differentials

When scholars first began studying cohabitation, researchers were interested in the characteristics of people who cohabit versus those who do not. Emphasis was placed on attitudinal factors (e.g., liberal vs conservative gender ideologies) and socioeconomic differentials (Smock, 2000). Today, because most people cohabit, questions about differentials tend to revolve around the issue of who does not cohabit and the different role that cohabitation plays in family formation by social class and for different racial and ethnic groups. Regarding the former, couples marrying without living together first tend do so because of religious beliefs, including individuals living in geographic areas with high levels of religious homogamy.

Regarding the latter issue, there is little difference in the likelihood of cohabiting along racial and ethnic lines, with two exceptions. One is that Asians are less likely to live together outside of marriage. A second is that more U.S.-born Hispanics report having ever cohabited (56%) than foreign-born Hispanics (49%) (Kennedy and Bumpass, 2008). What does differ in terms of race and ethnicity is whether a cohabiting

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31081-9

union evolves into a marriage. Specifically, fewer cohabiting non-Hispanic blacks or Hispanics marry their partners than whites (Zeng et al., 2012). Among Hispanics, this pattern is largely due to more couples remaining in long-term cohabitations than transitioning to legal marriage. Among non-Hispanic blacks, this pattern is explained by more couples dissolving their cohabiting unions than remaining together.

One important issue interconnected with race and ethnicity is economic circumstances. In the United States, on average, whites are economically better off than blacks or Hispanics. Researchers use various terms when studying the connections between family patterns and economic circumstances (e.g., social class, socioeconomic status) and measure it in various ways (e.g., educational attainment, income).

The bottom line is that people with more money and education are more likely to transform their cohabiting unions into marital ones. This finding is consistent with a large body of research showing that getting married, and staying married, is positively related to economic well-being. Consider the differential in the percentage of 22- to 44-year-old women whose first union was cohabitation. While cohabitation increased for all educational groups, there is a striking educational gradient; recent data indicate that 48% of women with college degrees experienced cohabitation as their first union compared to 70% for women who did not complete high school. People with college degrees are also more likely to use cohabitation as a step toward marriage; they have the highest chances of marrying their cohabiting partners compared to their less educated counterparts (Copen et al., 2013).

Major Research Issues about Cohabitation

The Rise in Cohabitation

The steep rise in cohabitation has several sources. Scholars view cohabitation as part of a constellation of family change that has swept the US and other Western countries over the past several decades. These changes include rising levels of divorce, increases in nonmarital childbearing, and delays in marriage. Scholars consider both cultural and economic factors to be important in understanding the increase in cohabitation (Smock, 2000). The former includes factors such as rising individualism and secularism, with a growing emphasis on the importance of achieving individualistic goals (Lesthaeghe, 1983). Economic factors include macro-level changes such as industrialization and women's changing role in the labor market. Also important has been the sexual revolution. Once premarital sex became acceptable, cohabitation became destigmatized (Bumpass, 1990).

An additional factor is feedback loops. What this means is that the various trends are reinforcing. High levels of marital disruption demonstrate that marriage is not necessarily permanent, resulting in more people opting for cohabitation. If childbearing outside of marriage is common, it then becomes clear that marriage is not the only possible or appropriate context for childbearing.

At a more micro-level, couples appear to choose cohabitation for numerous reasons. Some are practical matters such as convenience (e.g., the couple is already spending significant time together), the ability to live more cheaply, or as a test to evaluate whether the relationship is marriage material (Sassler, 2004; Huang et al., 2011). Importantly, it offers many of the benefits of marriage such as income-pooling, companionship, sexual access, childbearing, and childrearing. Studies also indicate that many young adults may want to marry but choose cohabitation or remain cohabiting until they feel ready. In particular, young adults wish to be in a financially stable situation before considering marriage. The perceived requirements include having enough money to afford a house and mortgage, having a stable job, saving sufficient money for a wedding and reception, and not living paycheck to paycheck (Gibson-Davis et al., 2005; Smock et al., 2005).

Measurement

To study a phenomenon, it has to be measured. National surveys began to gather detailed information about the cohabitation experiences of individuals in the 1980s. Arguably, the survey that spawned an enormous amount of knowledge about cohabitation was the 1987–88 National Survey of Families and Households. It obtained full cohabitation histories from a nationally representative sample of adult women and men ages 19 and up, setting the standard for future surveys. Still, until the 1990s, many national data sources, such as the U.S. census, did not directly measure cohabitation. Instead, scholars inferred cohabitation from other types of information about household members and the composition of the household. For example, if there was a two-person household comprised of a male and a female and whose ages were fairly close, researchers would infer cohabitation.

Though numerous national data sources now directly measure cohabitation, many challenges to accurate measurement remain. Marriage is relatively easy to measure. People may have a wedding or go to the courthouse, and there is a legal document with a specific date of marriage. This is not the case for cohabitation. Family scholars have thus studied how cohabitation is measured in surveys and in other data sources, and have played a role in changing how it is measured. Qualitative work has been extremely useful in this endeavor. By asking open-ended questions, qualitative work can delve more deeply into people's cohabitation experiences than close-ended survey questions.

Several conclusions have emerged from this work. First, cohabitation is often a gradual slide than a living arrangement associated with a particular start date. It may begin by spending weekends together and slowly move toward living together full time. Thus, people do not necessarily know exactly when they started cohabiting. Second, cohabiting couples are not accurately measured in surveys and census data that define relationships through ties between each household member and a specific household 'head' or reference person. That is, the convention was that every person living in the household was identified in terms of his or her relationship to the household head or reference person. If a cohabiting couple existed in the household but the reference person was not a member of the cohabiting couple, the existence of that couple was missed. This includes situations in which the couple resides with roommates, parents, or other relatives. Research showed that these missed couples were more likely to be economically disadvantaged and more likely to have children, groups of great

interest to scholars interested in families and their well-being. Third, major data sources such as the Census use the term 'unmarried partner'; qualitative work suggested that this was not a term people understood, let alone one that cohabitors would use to describe their relationships (Manning and Smock, 2005).

At least in part as a result of this work, the Current Population Survey (CPS), an ongoing survey that is part of the U.S. Bureau of the Census, made some major alterations regarding cohabitation measurement in 2007. It added a direct question about cohabitation, asking if the individual was currently living with a 'boyfriend/girlfriend/partner,' allowing researchers to capture cohabitations in which the reference person was not part of the couple. There were also improvements that led to being able to identify the relationship of all children in the household to their parent(s). Such changes have been significant. In 2008, 5% of all cohabiting unions in the CPS were between two household members that did not include the reference person. Moreover, the addition of the 'boyfriend/girlfriend/partner' question captured 20% more cohabitations than the 'unmarried partner' question (Kennedy and Fitch, 2012).

Continuing challenges include the lack of a clear start date, and, not surprisingly, inconsistency in reports of whether a couple is actually cohabiting depending on which member of the couple is asked (Waller and McLanahan, 2005). Another issue is the timing of data collection. The accuracy of cohabitation histories decreases as the span of time between the cohabitation and the date of interview increases (Hayford and Morgan, 2008).

Children and Cohabitation

Cohabitation commonly involves children. About 40% of cohabiting-couple households include children; this is about the same as the percentage of children in married-couple households. Up to one-half of children born in the early 1990s will live in a cohabiting-parent household at some point in their childhood (Bumpass and Lu, 2000; Kennedy and Bumpass, 2008). One way for children to experience this family form is by being born to a cohabiting couple. This trend is on the upswing. The percentage of all U.S. births that were to cohabiting parents increased from 6% in the 1980s compared to about 20% today (Bumpass and Lu, 2000; Lichter, 2012). Overall, the percentage of births taking place outside of marriage is 40%. Now the majority of these births are to cohabiting couples rather than to single women.

A central focus of research on cohabitation and children is whether cohabitation is harmful to children. In general, comparisons of children growing up in cohabiting versus married households suggest that cohabitation has some negative effects on child well-being. While many children fare well in cohabiting households, parental cohabitation has been linked to a range of negative outcomes such as increased odds of teen pregnancy for girls, poorer educational outcomes, and more behavioral problems.

At the same time, it is not clear that parental cohabitation itself causes worse outcomes for children. In other words, children experiencing parental cohabitation have some disadvantages to begin with compared to children born to and raised by married couples. One difference is economic; cohabiting families have lower incomes than married-couple families. The connection between parental cohabitation and child well-being is also partly explained by family instability, that is, by the parents dissolving their relationship. It is well documented that family instability tends to have negative consequences for children, with children typically doing best in stable family structures. Children born to cohabiting parents are five times more likely to see their parents breakup within 3 years of their birth than children born to married parents (Osborne et al., 2007). It is important, however, to be cautious about the generalization that cohabitation may not be in children's best interest. The quality of the cohabiting parents' relationship has been found to be very important and positively linked to parental engagement with the child (Carlson et al., 2011).

Cohabitation and Marital Stability

For many years, studies showed that premarital cohabitation raised the likelihood of divorce: the chances of divorce were higher for people who had previously cohabited either with their future spouse or someone else. This was demonstrated in many studies and most of those studies took into account other factors that might also raise the risk of divorce (Smock, 2000). Two explanations were posed to account for this pattern. The first was that cohabitation affected people in ways that made them more likely to end a marriage. The idea was that living in a nonmarital family form could change people's attitudes about the centrality and permanence of marriage. The other explanation was that premarital cohabitation drew people with values, attitudes, or other qualities that potentially made their marriages more fragile. For example, cohabitors tended to be less religious with less conventional family values than people who did not cohabit.

A shift in what appeared to be a solid finding has occurred as cohabitation has become the modal experience. Indeed, studies using recent data are overturning conclusions about premarital cohabitation and increased marital instability. One study reports that the positive link between premarital cohabitation and marital instability has decreased for more recent birth and marriage cohorts and that cohabitation does not appear selective of individuals with higher chances of divorce. Another finds that for marriages begun in the late 1990s and later, premarital cohabitation is not associated with divorce for either women or men (Manning and Cohen, 2012; Copen et al., 2012). It has also recently been shown that premarital cohabitation may even make remarriages more stable and less likely to dissolve (Reinhold, 2010).

Conclusion

Recent decades have seen sweeping changes in the family, perhaps none more striking than those related to nonmarital cohabitation. In addition to tremendous increases in the prevalence of cohabitation, it is also increasingly a context for childbearing, suggesting erosion in the dominance of marriage. Indeed, it has been argued that marriage is becoming 'deinstitutionalized' (Cherlin, 2004). However, another way to understand family trends is that neither marriage nor

cohabitation is institutionalized in the way that marriage once was. That is, while there still may be differences between cohabitation and marriage, as demonstrated by most people valuing marriage, hoping to marry, and eventually doing so, people are increasingly writing their own scripts about family formation and the meaning of families.

Family patterns are constantly evolving. As scholars have noted, studying families is akin to studying a continually evolving phenomenon (Seltzer, 2004; Smock, 2004; Smock and Greenland, 2010). Thus, in the years to come our understanding of cohabitation and its implications for individuals and for the broader family landscape will shift as well. All that seems certain is that cohabitation is not going away.

Cold War: Impact on Social and Behavioral Sciences

Hamilton Cravens, University of Minnesota, Minnesota, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Cold War encouraged the development of engineering and behaviorally controlling assumptions, concepts, and methods in the social sciences, especially in the United States and the nations in its orbit. Globalization and the multiple perspectives it revealed ultimately overrode Cold War notions and nostrums.

Cold War's Impact

What was the Cold War's impact on the social and behavioral sciences? Many historians argue that the Cold War began in 1947 and ended in 1991. It was the bipolar competition between the United States and the Soviet Union, together with each nation's allies, between each alliance, and for the allegiances of the remaining 'neutral' nations. (Gaddis (1972), especially pp. 283–362, the standard conservative view; for provocative and contrary views of the Cold War's duration and characteristics, see several of the essays in Joel Issac and Duncan Bell (2012), especially pp. 19–50, 91–141, et passim. It could be argued that the Cold War's impact on the social sciences lasted much longer than the Cold War itself.) In the late 1940s and early 1950s the United States cemented Western Europe in its orbit, together with several Asian states, including Japan, South Korea, and South Viet Nam. The Soviet government kept almost all of the Red Army's wartime gains in Eastern Europe, although in time it permitted West Berlin to remain free and Austria to be neutralized. Each superpower attempted to impose or insinuate its preferred social, political, and economic systems on each of its subordinate or allied states. Those associated with the United States formed democratic, market capitalist societies, with social welfare systems, while in the Russian bloc, Soviet forms of government, enterprise, science, education, culture, and social welfare were imposed from Moscow.

In assessing the impact of the Cold War on the social and behavioral sciences, we must realize that there were important differences between the impact of the Cold War in the Western world, and in the Communist nations, chiefly the Soviet Union, its Eastern European satraps, and the Peoples' Republic of China. National intellectual and political differences made for different results. And there were differences in the 'underdeveloped world,' as in Latin America, and in the areas emancipated by post-World War II decolonization, as in parts of Asia, notably India, and the Middle East. The picture is very complex. Not all nations experienced the development of the social sciences at the same time in history. Most social sciences existed before the Cold War began. The Cold War had an enormous influence in reshaping and expanding the social sciences' character: their approaches, research agendas, funding possibilities, and all manner of other uses for public and private enterprises. It also sparked critical, even opposite, reactions, such as democratic Marxist movements in the West and its allies, and dissent in the Communist world.

Impact of the Cold War in the Americas

In the United States, the federal government underwrote much behavioral science research in economics, political science, area studies, psychology and sociology and related endeavors through various agencies and departments of defense, intelligence, science, and medicine. The number of dollars available for social and behavioral science research and practice from private philanthropy was perhaps one-tenth of that available from federal sources in a typical year during the Cold War.

Within the U.S. social sciences, there was the emergence of the behavioral sciences, clearly a Cold War product, from its Second World War origins as a kind of engineering social science to devise methods and approaches to win the global conflict. The behavioral scientist, as distinct from the social scientist, sought to create rigorous methods, often informed by high mathematics, for understanding and predicting the behavior of individuals, of groups, of institutions, and of entire nations; the social scientist, traditionally, sought to gather information and to explain what happened or what would happen. Social scientists had used descriptive statistics since the mid-nineteenth century. Behavioral scientists went further and deployed sophisticated probability techniques and applied methods from inferential statistics. In the 1950s and 1960s, to take one example, political scientists experienced a 'behavioral revolution.' They imitated natural scientists in the sense that they employed formal classifications, correlations, appeals to synchronic systems and structures, as well as the formal location and purpose of units within larger political systems. They moved away from prior developmental historicism and toward a neopositivist empiricism. They often used one or another modernization scheme when talking about comparisons between the developed and the underdeveloped worlds – between political cultures in the industrialized West and the preindustrial 'third world.' Implicit was often the shopworn assumption of the general superiority of the West over the preindustrial regions. Thus were absolutist patriotism and scientific positivism parallel underlying assumptions of American social and behavioral science. The domestic and international tensions of the Cold War simply magnified these attitudes. In the 1950s, American fears of potential Soviet nuclear parity – later proven to be false – drove Americans, whether social scientists or not, to intensify their opposition to Soviet aggression on all fronts, real and perceived.

Although the Cold War introduced new issues and inspired new techniques, such as futures studies or game theoretical

nuclear war strategies, basic political attitudes and cleavages were not so much changed as intensified, especially a heightened patriotism and a worshipful faith in scientific and engineering rationality – scientific positivism, that is. Thus American sociology was divided into various camps. The structural–functional school of Harvard's Department of Social Relations, led by sociologist Talcott Parsons, emphasized the adjustment of the individual to the larger social system, and Robert K. Merton, of Columbia, promoted a similar but more modest version adjustment according to theories of middle range application. These might well characterize the posture of the postwar liberal in American politics. More radical were sociologists who followed the social conflict ideas of Lewis Coser, who insisted that conflict among differing social interests, or groups, constituted the warp and woof of society. Even more radical were C. Wright Mills, of Columbia, and his hardy followers, who declared that the social system had been taken over by powerful oligarchies and elites and that the average 'mass man' had little agency in society. Alvin Gouldner insisted that mainstream sociology simply upheld the status quo. All were fierce critics of Cold War conservatism, as well as what they believed was social science that buttressed Cold War conservatism.

Economists were similarly split into several camps. The macroeconomists who followed John Maynard Keynes had the experience of the 1940s to the 1970s to show that their aggregate demand economics did lift employment and produce prosperity; World War II and the Cold War sparked such great government spending which, together with certain tools, such as national income accounting and specific mathematical theorems, spelled unparalleled economic growth for the United States. Yet there was at least one other kind of economics, neoclassical microeconomics, or the study of the individual agent or firm in a market, which feted a philosophy of individualism, not the aggregate, whose proponents pushed it into the terrain of abstract mathematics, and rigorous axiomatic logic, thus laying claim to a higher level of scientific, positivistic economics. With the problems of 'stagflation' of the 1970s in the economy, the neoclassicists bested the Keynesians in their discipline and in the public arena. Hence partisans of conservative neoclassical economics won out in the 1980s and early 1990s, as the Reagan Administration scuttled détente with the Soviets and the Cold War heated up, as it had not since the later 1960s. There were also 'heterodox economists': they included libertarians, who wanted to wish government away; Marxist economists, who pined for social democracy; and 'post-Keynesian' economists, who worked to convince others that Keynes's doctrines had a rigorous mathematical, as well as a policy basis, and better for all than the dog-eat-dog ideology they accused the neoclassical economists of peddling. But this strange assortment of 'heterodox economists' could only agree among themselves that the neoclassical conservatives were wrong; by the 1990s they were split into warring groups themselves among post-Keynesians, libertarians, feminists, and Marxists – among others.

Development of the neutral or 'underdeveloped' world was also a part of hemispheric social and behavioral science. The trailblazers were likely the anthropologists, who during the 1940s and 1950s, turned from the study of man's origins with preliterate tribes to the study of contemporary peoples in exotic areas of strategic importance to the United States. The Cold War made such work even more crucial to American policymakers, who believed the nation was engaged in a twilight struggle, as President Kennedy put it, for the 'underdeveloped' world's allegiance against the Communist menace. According to Walt W. Rostow, sometime economic historian and presidential adviser, all nations followed certain stages of economic growth to urbanization and industrialization; this became high policy with which to thwart Communism and to promote democratic capitalism around the globe. During the Cold War, the United States' military, intelligence, and international development agencies funded numerous social science investigations in the 'underdeveloped nations' seeking, in the case of South Viet Nam, to support the Diem dictatorship, or in the case of Chile, to carry out through 'Project Camelot,' a study of how to design a general systems model to predict and control internal strife and promote counterinsurgency in peripheral countries. In any given time there were perhaps several dozen such covert social science operations functioning with governmental support.

Some social science expertise was indigenous in Latin America. The nineteenth century independence movements fostered champions of liberal statism, Comtean positivism, and German historical or institutional economics. Between the Second World War and the 1970s, as Latin America entered the world economy, its economists, whether proficient academically or self-trained, wrote much about the economics of underdeveloped countries and regions – that is, their region. For example, the left-liberal Argentine economist Raúl Prebisch developed from the 1940s on a center–periphery theory of economic underdevelopment that was both theoretical and historical, that social scientists and governmental *apparatchiks* throughout Latin America took up. He also created a network of like-minded economists through the Economic Commission for Latin America (ECLA), located in Santiago, Chile, and which nurtured a Latin American economics profession anxious to promote its region. Certain groups of United States economists, as the neoclassical economists at the University of Chicago, established rival groups of conservative economists, as at the Catholic University of Chile, who went on to advise the region's rightist regimes, such as Pinochet's in Chile. Here the regional stimulus was Fidel Castro's Cuba, against which both the United States and the rightist regimes reacted, plotted, and schemed. The Cold War definitely spilled over into the Western Hemisphere. The social scientists, as retainers of various governments, smartly followed behind their patrons.

The Impact of the Cold War in Western Europe

Before the Second World War, social science's intellectual center was Europe. On the European continent, dictatorships arose in the interwar and war years from Iberia to the Urals, save for England, France, and a few neutrals, such as Switzerland and Sweden. Whether these dictatorships were Fascist, National Socialist, or Marxist-Leninist, their leaders destroyed or drove into exile most of their social sciences – and practitioners. Only those social sciences that pleased the dictators, such as eugenics in Nazi Germany, or eugenics and psychology in the Soviet Union, survived the war years. Thereafter consequently the United States became a world power in the social

sciences, thanks in addition to its expansion and mobilization of social scientists. Europe's distress was America's advantage.

In postwar Western Europe – the areas allied with the United States and liberated from Nazi or Fascist control – there was a rebuilding of society and economy, thanks in no small measure to the Marshall Plan. Everywhere the Americans there behaved much as they did at home, so that national autonomy and democracy emerged in Western Europe. There the masses demanded, and got, sometimes with the threat of Communist influence, a new deal of social welfare legislation which in turn necessitated the training and employment of social scientists to administer the new states' social welfare, economies, political democracies, and defense forces, in the form of the *North Atlantic Treaty Organization* (NATO), formed as a *cordon sanitaire* against the engorged postwar Soviet empire to the east. The Western European countries demanded NATO from the U.S. as the price of the founding of the West German Republic in 1949 and its rearmament in 1955. Thus an American empire was created there, but by mutual consent and invitation, not terror, coercion, or imperial rule from Washington, as was the case in Soviet-controlled Eastern Europe.

Hence the social sciences in Western Europe followed both national traditions and American influence, with the latter usually secondary. Thanks to the American influence, or lack thereof in other cases, the Cold War stimulated an intellectual renaissance. In Great Britain, for example, sociology came into its own, even appearing in Oxford and Cambridge by the 1960s; initially British sociology followed American patterns, but after 1970 other, more indigenous traditions, often ruggedly empiricist, reasserted themselves. The American influence could be felt mainly in institutional forms, as in disciplinary departments and formal associations. On the Continent, American and European traditions clashed and melded. Thanks to American influence in the United Nations Economic, Social, and Cultural Organization (UNESCO), American forms of social science organization, as in disciplinary departments and associations transferred to the Continent, but theory was a different matter. In France, the Marxist influence on sociology was evident, as were the ideas of Michel Foucault and others. In West Germany, American intellectual traditions vied with indigenous ones, such as the returned social science exiles, such as the Frankfurt School, but also conflict theorists such as Ralf Dahrendorf. And there were democratic Marxist social scientists as well, thanks in some measure to the Social Democratic Party. Anthropology in America became focused on contemporary cultures, whereas anthropology in Europe tended to focus on the effects of colonization. American anthropology became useful to the nation's cold war social sciences, whereas European anthropology was largely oriented away from the Cold War's direct influences.

Two disciplines in particular, psychology and economics, betrayed Cold War influences but also became international technical behavioral sciences. Psychology became increasingly Americanized. In West Germany, professors from the Nazi era retired only in the 1960s, when a younger generation emerged, insisting on American-style psychology, meaning data-driven research and statistical treatment of results. In Britain, psychology closely paralleled the American version. And by the 1970s, everywhere else in Western Europe, the Anglo-American synthesis of cognitive behaviorism dominated. Economics also mutated into an increasingly technical behavioral science, which split into conflicting macroeconomic and microeconomic branches, often with the former pushing a Keynesian or post-Keynesian agenda, and the latter an updated version of Austrian individualistic economics. The technical methods psychologists and economists used made their sciences international, but the methods themselves were largely American and Cold War-inspired in origin. If the technical innovations were largely a Cold War legacy, their cosmopolitanism betrayed both American and European elements. Thus the Europeans retained a sense of society as a collectivity, whereas the Americans' underlying attitudes always retained some agency for individuals – and individualism.

The Impact of the Cold War in the Soviet World

Josef Stalin suppressed most of the social sciences in the Soviet Union well before the Cold War. He would not tolerate sociology, law, political science, or economics, unless derived from his notions of Party orthodoxy. The construction of a Soviet centralized system of science permitted only one social science – psychology – some latitude, largely because Ivan Pavlov's work had been reconciled with dialectical materialism, the Party's official philosophy. Dialectical materialists sought to explain the world by insisting that all that exists is real; the real world exists as matter–energy; and this matter–energy develops in accordance with universal regularities or laws. They thus refuted idealism, especially the Western versions. Yet ironically dialectical materialism permitted Soviet scientists to engage in philosophical jargon – 'newspeak' – that in turn permitted considerable flexibility, as well as camouflage for scientific discourse safe from Party censors' onslaughts. Thus Soviet psychologists rehabilitated consciousness and other mental constructs justifying attempts to create a new 'Soviet personality,' a Party priority, and Soviet cybernetics, again a patriotic necessity, developed from 'newspeak' discussions among those to compete with America in computers (Slava Gerovitch, 2002: Chapters 1–6). Cybernetics was indeed a Cold War interdisciplinary behavioral science.

The Soviet imprint was manifest on the social sciences in its satellites in the Cold War era. The social sciences received less funding and more intellectual control than other sciences, thanks to the monopoly of the Communist Party in each country. The Russian occupiers made sure their hierarchical and centralized system of government institutes of science was created in each satellite. The Party governments in each country used the social sciences to enforce Party hegemony. Results differed from country to country. In East Germany, for example, until the 1960s, Party officials permitted Nazi-era psychologists to retain their chairs on the Leninist ground that bourgeois scientists could work for the Party; as this generation retired, indigenous devotees of Soviet psychology replaced them. Yet even these professors mixed Soviet-style cognitive research with American information-processing approaches as a new 'Marxist' approach congruent with the indispensable current 'scientific–technical revolution.' Poland's

national consciousness was the strongest in Soviet Europe. Catholicism and repressed Polish national pride kept Polish intellectuals free in their private thoughts, at least; and whatever had the imprint of the Russian bear was distasteful to most Poles. Polish social science during the whole period was more up to date with Western social science than social science in other Soviet satellites. Psychology flourished in Poland as the study of national character, seen as a collective entity. Even before the Soviet collapse, Poland was an unreliable ally, as the emergence of the labor union Solidarity in the 1980s suggested. Often the social sciences were weak in some satellites, such as Bulgaria or Yugoslavia, and the imposition of Soviet orthodoxy came easily. Yet in all the satellite countries, the social scientists turned inward, toward studies of their own national character; commonly they paid mere lip service to Moscow. In this way they gained some distance, some breathing room, from Marxist-Leninist orthodoxy. Hence the Cold War had an enormous impact, institutionally and, to a lesser extent, intellectually, upon Central and Eastern Europe, especially with the establishment of Communist governance, something that the Soviets had known since Stalin consolidated his rule in the late 1920s in Russia.

The Impact of the Cold War in Asia

Among Asiatic Communist states – chiefly the People's Republic of China and the Democratic Republic of North Korea – the social sciences were completely under the thumb of their dictators and Party officials. Neither Mao Zedong nor Kim Il-sung would permit competition with their social doctrines. In the 1930s, however, Chinese social scientists had imported Western social science to facilitate the country's modernization, especially in sociology and economics – precisely the fields that Mao would commandeer and submit to his ideas. Hence in the Cold War era, non-Communist social scientists retreated to Taiwan and Hong Kong. In Taiwan, those who retained an ideological affinity with the mainland were suppressed. In Hong Kong, thanks to British colonial traditions of political stability and academic freedom, Chinese social scientists developed their teaching and research often along the lines of American and British social sciences, where many had received their postgraduate training. In South Korea, at first the social sciences were a pale imitation of the American social sciences, especially sociological structural–functionalism and conservative microeconomics. Eventually, as South Korea's political culture became increasingly democratic, so its social scientists began to study problems facing their nation, such as national division, the status of a postcolonial society in the world economy, and related issues.

Two major Asian states, Japan and India, demonstrated much about the Cold War's impact beyond the Americas and Europe. In the early postwar years Japan's American occupiers democratized society, politics, and the economy, although Japanese cultural traditions of collectivity, obedience, and central authority remained below the surface. Social scientists then wished to eliminate Japan's negative history and reputation, and adopted many American social science ideas and methods. Yet in the 1970s and beyond, Japanese Marxism, a product of the 1920s, was revived as a way to reassert Japan's intellectual identity apart from Western influences. Japan was doubtless an American ally in world politics, as were the nations of Western Europe, which tilted the Cold War toward the United States. Yet there was a reassertion of Japanese cultural and intellectual identity and independence, married with American-style disciplinary formation and institutionalization.

With British rule in the eighteenth century came a rich and complex tradition of social research – for administrative and imperial purposes, to be sure – in India. After independence in 1947, Indian sociologists and anthropologists at first gravitated to American-style structural–functionalist analysis of modernization. They focused on rural communities undergoing social change. The village they assumed was a functional unit with different caste groups, factionalism, class antagonisms, patron–client relations, and the relation of the village to the outside world. The University of Chicago's sociology programs heavily influenced these scholars. One could also see the influence of structuralism in studies of caste, kinship structure, ritual, and religious practices and beliefs. Yet there was also a growing interest in the use of Marxian methods of social and economic analysis. In economics, independence brought forth the problem of national economic development, and in the early postwar years there was much interest in government planning of the economy. Indian social scientists sought to conform to international standards of excellence, which meant they looked toward the United States, Western Europe, and Japan, not the Communist world, for their ideas. In part due to the British influence, Indian economists used statistical investigations of Indian economic life to help central planning. Economists such as Amartya Sen and others asked basic questions about equity and justice in Indian modernization. From the 1970s on, government planning fell into disfavor and economists began asking more specific questions about, for example, whether agriculture promoted or retarded development, about whether government promotion of industrialization was beneficial or harmful, the role of technology, and the impact of the world economy and of foreign investment on Indian economic growth. Indian political thinking was predominantly liberal, and this was reflected in its governmental structures and among its political scientists. Indian political scientist Rajni Kothari, for example, insisted in 1970 there was a dynamic core in the Congress Party's dominance of national democratic politics. Using a structural–functional analysis, Kothari argued that the "Congress system" connected government and party at different levels, from the nation's capital to the cities and the rural hinterlands. This accommodated dissent and helped stimulate needed correctives. Yet, perhaps inevitably, there was criticism from an indigenous Marxist social democratic left, not unlike developments in Western Europe and Japan, and left-liberal Marxian analysis informed dissent among Indian social scientists and politicians.

Conclusion

What, then, was the impact of the Cold War on the social and behavioral sciences? It encouraged, from developments in the Second World War, a positivistic, manipulative, and engineering approach to human behavior in all its dimensions. While the Cold War was in its early, intense phases – until the

resolution of the Berlin and Cuban missile crises of the early 1960s – the social and behavioral sciences closely mirrored the values and remedies of their sponsoring central governments. These political and intellectual straitjackets began to fray and dissolve outside the Communist world by the 1970s, thanks to liberal and radical dissent in the United States, in Western Europe, in Japan, and even in India, and if the Cold War idea of using social science for social engineering maintained its vitality, the Cold Warrior attitudes diminished considerably, and national differences and preferences asserted themselves. In the Communist world, it was only when the Soviet Union collapsed, and China came under Mao's successors, Marxist-Leninist rhetorically but nationalistic and capitalistic in fact, that matters changed. In Central and Eastern Europe, each former satellite retained, to some extent, Russian-style centralization of cultural life, but the expansion or reinvigoration of universities promoted Western-style standards of social science teaching and research, again, with each nation's elite asserting its distinctive national cultural identity. In the People's Republic, social science that supported the nation's development, for example, sociology and demography emerged from the Party's stranglehold.

An indirect influence of the Cold War, and not just in the United States, was the rise of ideologically driven think tanks, such as the right-wing Heritage Foundation in the United States, which employed social scientists as spokespersons for their ideas to influence public opinion and governmental policy. As such the think tanks came to challenge the intellectual authority of the social and behavioral sciences in academic and even government academy circles. Here was Cold War social engineering, often financed by private interests, creating potentially powerful Non-Governmental Organizations (NGOs) that could direct or redirect public policy along risky, even dangerous pathways, with little, if any, influence from ordinary citizens. The United States likely had the most such think tanks. There was no small irony in this, for throughout the nineteenth century, and into the twentieth, American social science was often a folk movement, democratic to the core.

In conclusion, the Cold War dominated certain aspects of the social and behavioral sciences around the globe for some years, but clearly after 1970 or so, and especially with the passing of Mao in China and much later, the collapse of the USSR, the Cold War was in the main a memory, and not always a pleasant one to those involved. Yet in the long perspective, the world's peoples had become increasingly aware that they were living in a global civilization. The Cold War obscured and retarded that perception for several decades. But the fact of globalization trumped Cold War perspectives. Now the world appeared highly diverse, constituted of *n*-dimensions, proportions, and images.

Abstract

The term refers to the epoch between 1947–48 and 1989–90. The persistent central feature of the Cold War is the global contest between the United States (US) and the Soviet Union (USSR). The major changes in the structure of the contest are the transformation of the confrontation in Europe into stability, cold peace on the basis of the status quo since the mid-1950s, and the reversal in China's posture from principal ally of the USSR into expedient cooperation with the US. This article explains the longevity of the Cold War concept, the different perspectives on how the major powers ended and reignited the tensions, and what threat perceptions and resulting actions produced the structures of the East–West conflict.

The term is widely accepted in historical writings. It refers to the epoch between 1947–48 and 1989–90. The nature of the Cold War, its causes and effects, and the reasons for its long duration are, however, controversial. Its meaning would exclude Asia because of the outbreak of wars there; the wars in Korea, Vietnam, and Afghanistan made a difference to how the United States (US) and the Soviet Union (USSR), the two superpowers, waged their global contest in Europe. The situation in Europe resembled neither peace nor war; *East–West Conflict: Confrontation and Détente* expresses the ambiguity, but this label is less eye-catching.

The Concept and Its Salience

The persistent central features of the *Cold War* are the global contest between the US and the USSR, the dependence of the allies on the security guarantee of their respective superpower, and bipolarity. The latter was reinforced in the core area, the arms race, due to the widening gap between the extensive and highly diversified weapon systems of the superpowers and the arsenals of Britain, France, and the Peoples' Republic of China (PRCh), the other three established nuclear powers. This explains that American and Russian writings hold to *Cold War* as a concept fitting the entire epoch. It allows for distinguishing between moments of imminent war – Cuba, October 1962, and Yom Kippur War, October 1973 – times of high tensions and war outside Europe – Korea, 1950–53; Vietnam, 1964–75; Afghanistan, 1979–88 – long intervals of *détente* (Relaxation of tensions. Détente policy aims at making agreements that are trustworthy because both sides have incentives to keep them. The assumption is that 'security' could only be found through political means, and on a mutual basis) – highlighted by summit meetings and major arms control agreements – and even moments of concerted crisis management (June 1967 Near East war) or collaboration (during the Laos crisis and Vietnam War in the 1960s and ending wars in Africa in the late 1980s).

This version pays less attention to the fact that throughout the four decades not all parties to the Cold War were involved on the same issue-at-stake and at the same time. France joined Britain (UK) and the US in 1948 in founding the West German state as the Western allies' response to Stalin's anchoring of Poland, Bulgaria, Romania, Hungary, and Czechoslovakia firmly into the Soviet security-zone, and maintained staunch opposition to proposals for a neutralized, but nationally rearmed united Germany (Hitchcock, 1998). Since the mid-1960s, France became the spokesman for a Europe less dependent on the US and discussing terms of settlement with 'Russia.' The Federal Republic of Germany (FRG) converted *Cold War* into *cold peace* with the ratification of *Ost-und Deutschlandverträge* (1970–73). Both governments cooperated in defending *détente* in and for Europe; by implication, this aspiration for a European peace zone rejected the American concept of the indivisibility of the global contest between East and West. The PRCh, the only principal ally the USSR ever had (1950–58/59), made its peace with the US in 1972 on Pejing's term of 'One China.' While the PRCh had provoked the US during the 1950s to continuous nuclear saber-rattling, it turned its antihegemonic posture throughout the 1970s and 1980s against the USSR.

The Components of the Term

The definition refers to four aspects of the conflict: (1) the ideological antagonism between the Western concept of freedom of choice for the people of the domestic regime and external alignments of their state and the Soviet-imposed monopoly of the 'workers' and land labor party and subjugation to the community of socialist states; (2) the geostrategic struggle for bases of power-projection; (3) the domestic political contest, but almost exclusively within Western countries, about commitments to the military alliance or equidistance to both of the superpowers; (4) the dispute about where to draw the line between permissible and noncompatible elements in the policy mix of market-oriented and government-controlled economies. Of these four components, the last became least important for refueling the confrontation; the convergence of the mixed economies rather promoted the idea that *Osthandel*, credit facilities, and technology transfer might enhance not only 'liberalization' in the East European economies, but also generate transformation of the political system.

The Ideological Antagonism

The ideological antagonism was the first impulse for *confrontation*, but it was also subject to changing threat

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96005-7

perceptions and shifts of emphasis in the balance between *confrontation* and *détente* in the overall relationship. The wider notion of *East–West Conflict* posits the Cold War as a distinctive period into the ideological struggle, originated in 1917–18, between the *Wilsonian Impulse* and Lenin's urge for peoples' democracy as the basis for securing peace (Link, 1980). From this perspective, Stalin and Truman likewise took the lead in splitting the world along 'alternative ways of life': Western definitions of *democracy* could not be reconciled with Soviet definitions of security (Lundestad); the latter implied that "whoever occupies a territory also imposes his own social system" (M. Djilas). Pursuing different policies, 'East' as well as 'West' nourished suspicions of the opposite's intention to extend its influence into the other's emerging bloc, the Soviets through encouraging Communist parties and the Americans via 'dollar imperialism.' Western leaders argued that the West had to learn its lessons from the vain hope to appease an expansionist regime. 'No more Munichs' informed the confrontation stance of *containment* as the West's answer to the external threat. (The term refers to the Munich Conference on 29–30 September 1938, where N. Chamberlain and E. Daladier conceded A. Hitler to proceed with the annexation of the Sudetenland and informed the Czechoslovakian government that it must either fight alone or abide by the Agreement. The notion 'Munich' conveys the message that dictatorships are unsatiable, that aggression feeds on weakness, that appeasement merely postpones the day of reckoning, etc.) The concomitant stance at the home front is based on the thesis that authoritarian regimes abuse state-power against large parts of their own population; therefore Communists must not be given a chance to occupy crucial positions of government such as Defense, Interior, Public Transport, or Justice.

Conversely, Communist ideology maintained that *capitalism* on the one hand inspires the state to prosecute the working-class and thus breeds *fascism*, and on the other hand is inherently expansionist (imperialist) and therefore knows no boundary to its domination. The belief, however, that capitalist nations are bound to fight for defeating rivals, made Stalin expect that Britain would resist the US' aspiration to become heir to the British Empire. The *new feature* of the post-World War II international system is that the US and the UK were competitive partners in founding the International Organizations destined to develop and monitor rules of conduct for international trade, currency exchange, and development aid (Gardner, 1969). The UK and France, but also Italy, expected the up-to-then reluctant US government to come to the rescue and infuse capital into the European economies as the only strategy which could render support to the parties willing to exclude Communists from governments (Lundestad, 1986). The formation of Western-oriented governing coalitions ensured that the European allies, as well as Japan, cooperated with the US in the evolution of the International Economy, to which the USSR and the PRCh were not negotiating parties after the outbreak of the Cold War. Most allies did not comply, however, with the American demand to restrict 'trading with the Communist enemy,' except in conspicuous moments of Soviet war activities.

The ideological component became a wasted asset after its overexploitation during the first phase (1947–53). Khrushchev's condemnation of Stalin's death toll in February 1956 and the NATO allies' perception that the Kremlin was unlikely to launch a general war on European territory (1956/57) put a break on the momentum of ideology as a driving force in the East–West conflict. But it was on the Kremlin to end the system conflict. In 1987, Gorbachev, determined to promote domestic reform and improve economic performance, rescinded the Breshnev doctrine and made it known that hard-liners in Eastern European governments should not reckon with Moscow calling on the Red Army to back up unpopular Communist regimes (Adomeit, 1998).

The Long Duration of the Cold War

For explaining the longevity of the Cold War, the account therefore has to focus on the other two factors: the structures which emerged with the consolidation and reaffirmation of the divisions of Europe and Germany, and the peculiarities of the military–geostrategic balance between the two sides.

The Divisions of Europe and Germany

The key feature is the hinge between the two *divisions*. The stark contrast between Stalin's refusal to consider concessions on Poland, Bulgaria, and Romania in exchange for American economic assistance and his demand to have a say on questions concerning primarily intra-West relations, e.g., the status of the Ruhr area or of Norway, provoked the US and the UK to tie their zones firmly to Western institutions (Deighton, 1990). The implementation of this basic strategy was, however, complicated by clashes of interest between the US, France, and Britain. These tensions prevented them from advancing as far as the USSR had with incorporating its German state, the German Democratic Republic (GDR), into the Soviet Empire. Hence they could not, as wanted, negotiate from a position of strength, but expected to be asked to give away on what 'the West' did not yet have, e.g., the FRG's defense contribution, whereas the USSR would persist in its refusal to put its reign over Eastern Europe on the agenda. The stalemate was compounded, when the reimposition of the Ulbricht regime in 1953 revealed that the Kremlin considered the GDR as its west-side lever for control over Poland and Czechoslovakia.

The structural impediment to a negotiated settlement disappeared when Moscow tacitly bowed to Germany's entry into NATO (1955) and when the 'West' acknowledged the fact that the USSR was strong enough to prevail in Eastern Europe (1956). German *Ostpolitik* put the final stamp to the 'normativity of the facts.' (Initiated by the Grand Coalition government under Kiesinger and Brandt and actively pursued by the SPD–FDP government under Brandt and Scheel, the FRG made an effort to end the special West German conflict with the USSR and the GDR within the overall East–West conflict. *Ostpolitik* was based on the assumption that the 'giant' to the East was an everlasting world power; besides, as the winner of the 'great patriotic war,' the USSR had to be accommodated. Bonn was prepared to acknowledge Moscow's quest for security 'from' Germany and to admit to the invulnerability of the post-World War II frontiers.) On this platform, the so-called Helsinki process, the Conference on

Security and Cooperation in Europe, lingered on throughout the 1973–89 period. Neither side was ready to proceed toward peacemaking.

The Cold War might have ended earlier if Gorbachev's predecessors had responded to the US view that Germany's double bind into a US-centered NATO and European integrated structures would prevent Germany from positing a threat to the security of the USSR (Schmidt, 1993–95). Instead, Moscow's attempts to push the divisiveness of nuclear diplomacy within NATO rather than wait for the outcome of such conflicts provoked the 'Atlanticists' to close ranks and reiterate the standard thesis that the West could prevent the USSR from winning the Cold War if its members resisted the temptation to court Moscow and make separate deals with the USSR. The Soviet leadership's 'stupidity' is said to have saved the US or NATO to get rearmament projects – such as NSC-68 or the 1979 dual-track decision – through.

The Peculiarities of the Military–Geostrategic Balance

The key feature is the fundamental asymmetry between the nature of America's and Russia's predominance in their respective sphere. This asymmetry is reinforced by the imbalance of military forces between NATO-Europe and the USSR's forward deployed forces (Kugler, 1993).

The advantage of the US in its global contest with the USSR was that all other principal powers, including Germany and Japan, were allied to the US. This helped in the buildup of the international economy, but not necessarily in defense. Consequently, the US diplomacy was absorbed as much in intra-West crisis management as in the context of East–West relations. The allies wanted to be assured that there were no long-term security risks involved for them in America's option for sponsoring the resurgence of the enemies and occupiers of World War II as strongholds of the West. Having imposed limits on Germany's and Japan's military status, the US could not reckon with a defense contribution for some years to come; both were prohibited to engage in 'out-of-area' defense activities (Schmidt and Doran, 1996).

By contrast, the USSR gained a formidable ally in the PRCh, who was keen to test the credibility of the American commitment to South Korea and Taiwan. Although the USSR copied the West's community building by setting up COMECON (1949) and the Warsaw Treaty Organization (1955), the Kremlin relied for exerting influence *de facto* on the penetration of the bloc partners' central agencies: the State Party, Secret Service, and top military echelon. The USSR also made sure through logistic measures that the Soviet military could operate from its allies' territory independently, and if need be without the consent of the incumbent governments (Wolfe, 1970).

The military imbalance between NATO-Europe and the USSR existed throughout 1947 until the mid-1980s. The US found no takers – except the FRG from 1961 onward – for its concept of balanced collective forces in the sense that the US were the sole provider of strategic forces, that is, weaponry projected to hitting targets located in the USSR, whereas the allies would recruit the ground forces and tactical air forces required for the defense of the region against infiltration or surprise attacks. Britain and France preferred to duplicate the US strategic role, albeit on a much minor scale, and took the relaxation of tensions in Europe and their entanglement in the legacies of their imperial rule as the rationale for reducing their force assignments to NATO.

The Intersection of Economic and Strategic Decisions: The European Structure

The failure of the 'Big Four' to cooperate on a German Peace Treaty is identified as a crucial turning point toward the Cold War (Leffler, 1992). Stalin did not want to give the impression that the US, thanks to the atomic bomb and its economic wealth, could impose its will on the USSR; he therefore pressed his claims on Iran, Turkey, during the Peace Conferences with Germany's wartime allies and in the Allied Control Council. This in turn was taken in Washington as a signal that hope of Russian cooperation must be abandoned. Truman and Byrnes had been reluctant to confront the USSR when the Cold War started over the fate of Eastern European nations (1944–47). Now, in view of the havoc, the 1946–47 crisis wreaked on the economies of Britain and France, the US government conceived that Western Europe could not save itself (Hogan, 1992).

From there on, the 'West' displayed a dynamic of its own. The first act was that the economic recovery of Europe was said to require the inclusion of (West) Germany; the price for getting France to change its German policy was the assurance that the US and the UK would back up the French quest for security against a resurgent Germany. The second act followed: Britain and France pleaded with Washington that the Marshall Plan initiative would not suffice to attain stability without an American security guarantee. Against the background of the Berlin blockade, Truman in October 1948 ordered that the US provide the major counterbalance to the 'ever-present threat of the Soviet military power.' In September 1948, the Brussels Treaty Organization (BTO) had already resolved that the defense of Western Europe should be as far to the east (of West Germany) as possible. Because this was beyond the means available to the BTO and not yet compatible with the military strategy of American and British defense planning, it was only a question of developments in the Cold War that the third issue be placed on the agenda: German rearmament. The logic behind the buildup of conventional forces sounded compelling: why do the old allies expect the US to provide ground and air forces and the Supreme Allied Commander to NATO's integrated forces with a view to realize the concept of forward defense when they deny the indispensibility of a sensible German defense contribution, on whose territory the French, in particular, wanted to stop the enemy's offensive? At that time, however, all the US military could offer was an air offensive to deter the USSR; they did not yet want to rely on 'the bomb' (Ross), and the USSR had acquired by then (Fall, 1949) an atomic capability. On 22 September 1949, the US-UK-Canadian governments jointly announced that an atomic explosion has taken place in the USSR.

The outbreak of the Korean War generated the fear of a similar war-by-proxy in divided Germany. The US did not only reverse its stance on what countries were of absolute importance to US security by now declaring Korea the test case

of what became the domino syndrome, that no US ally should fall prey to a Communist invader, but also designated the National Security Paper NSC-68 as the platform for a massive conventional rearmament of the US, adequate force deployment abroad, and military aid to upgrade the defense capabilities of its European and Asian allies (May, 1993).

The issue of German rearmament was divisive, but the US compromised with France on the understanding that German forces be integrated into a European Defense Community (EDC), whereas the EDC would delegate strategic planning and fixing force requirements to NATO. The project became the victim of French domestic politics; the US and the UK had to comply with the French request that no German soldier be officially recruited until France had ratified the EDC and German Contractual Agreements. The demise of the EDC meant that Washington had to forego the hope that US force deployment would be a temporary stopgap until the European allies, and especially the FRG, were able to do more toward meeting NATO's minimum force requirements.

The parallel staged fourth act (1952–54) produced the *definitive structure of the Cold War in Europe*: the NATO, to which the FRG was finally admitted, had made itself dependent on the credibility of the US (and the UK) strategic deterrent. This provoked the issue how the USSR would react to the logic that NATO's new member would have to be equipped with the same weaponry as the allied forces into which the German divisions were to be incorporated. Chancellor Adenauer made it clear that the FRG did not want to provoke Moscow unnecessarily by dislocating medium-range ballistic missiles on German soil, whose later replacements might be able to hit targets in Russia, but he and his successors insisted on having at least a crucial German vote in all decisions on the use of nonstrategic weapons in NATO's custody in case deterrence to all types of war failed (Heuser, 1998; Trachtenberg, 1999).

This final act of incorporating the two German states into alliances dominated by the nuclear-strategic superpowers had a far-reaching effect: plastering the 'frontline' states with short-range atomic weapons was the best insurance premium that the Germans would not launch war from their soil (Ullman, 1991). As long as the US and the USSR stationed troops there and resolved to maintain control over the warheads, the danger of accidental war could be excluded. The parallel to the military factor written into the strategic landscape is the interest of the Western nuclear powers in confirming the status quo and discuss on that territorial basis the questions of putting ceilings on rearmament. Separately, the two German states relaunched their rivalry and demanded (1955–73) allies and Third World countries alike to subscribe to the *Alleinvertretungsanspruch* of the Western democratic (FRG) or peoples' GDR. (Due to the resumption of diplomatic relations with the USSR (in 1955) as the last of the four powers responsible for Germany and Berlin as a whole, the (West) German Foreign Office (W. Grewe, W. Hallstein) considered it necessary to stipulate that the recognition of the GDR as an independent state (rather than the Soviet occupied zone) by states other than the USSR and the members of the Warsaw Pact must be taken by the FRG as an unfriendly act; undermining West Germany's pursuit of reunification. Subsequently the FRG would be forced to interrupt diplomatic relations and suspend foreign economic assistance. Conversely, the GDR urged members of the Warsaw Pact to support its claim for being the second German state. With a few, but crucial exceptions (Yugoslavia), the FRG succeeded in stalling the formal recognition of the GDR until the conclusion of the '*Deutschlandverträge*' and the admission of the two Germanys into the United Nations in 1973.)

The History of the Concept, Major Developments, and Empirical Results

The invention of the term is accredited to Walter Lippmann who took issue with G.F. Kennan's 'X'-article 'Sources of Soviet Conduct.' Kennan's long telegram of 22 February 1946 molded the agenda of America's containment policy. His arguments about Stalin's hostility of the West and unapproachability to conventional diplomacy were selectively used by top officials in Washington to assert that the 'Soviets' will develop all means and methods ranging from threat of military aggression via propaganda warfare to clandestine activities to a degree without precedent in history. Therefore, the US had to strengthen its executive branch, introduce a national security policy, establish a professional intelligence agency, and develop an unassailable military–industrial base (Leffler, 1992; Paterson, 1979).

The opposite Communist view emphasizes three aspects: the economic aggressiveness of the long-standing hegemonic US project to attain a 'one-world market' and abuse of the open-door doctrine for penetrating other nations' economy; the manipulation of anticommunism as a club to suppress claims for social justice and equality of rights within the American and other Western capitalist systems; and America's acquisition of bases bordering on the USSR for purposes of encirclement and monitoring inside the USSR. *In geostrategic terms the US became a direct neighbor of the USSR*, whereas the USSR required long-distance bombers (it introduced such jets by 1955) and intercontinental ballistic missiles to show the US its vulnerability. The strong engagement of the US in the post-1990 contests about Caucasian and Middle East oil and gas concessions and pipeline routes indicates that the US–USSR rivalry did not end with the Cold War.

The 'Revisionists' (LaFeber, 1991; Paterson, 1979) disclaim that Stalin pursued an offensive strategy aiming at extending Soviet rule; they discern rather the US' responsibility for causing the Cold War. Truman and his advisers (Acheson, Harriman, Lovett, McCloy, Nitze), intending to contain the self-opinionated coalition of leftists and isolationists at home and to exploit the economic preponderance abroad, is attributed to launch a military–industrial complex and a national security state in order to perpetuate American hegemony; this view is said to lead the US to march toward world power. The postrevisionist approach accounts for the Soviet aspect of the fundamental change in the Cold War since about 1954–55, and explains the US interest in *détente*, i.e., the coinciding interest in *Long Peace* (Gaddis, 1987). Moscow settled the Austrian question, tolerated the FRG's entry into NATO, and opted for reconciliation with Tito, the only East European leader who had got away with breaking ranks with Stalin. The cumulation point was the declaration of the doctrine of *peaceful coexistence*. The Western allies' match was tacit satisfaction with consolidating the status quo after they had absorbed the FRG.

Stability in Europe turned the UK's, US's, and France's attention to the Third World. In reaction to Communist China's revolutionary foreign policy, the Soviet leadership in 1960 declared wars of liberation from colonial rule legitimate and thus distinguished peaceful coexistence in the developed world from just wars in the 'southern' part of the globe. In this sense, the East–West conflict was exported to the Third World.

The US resolved on noninterference in the internal affairs of the Soviet bloc and relaxation of tensions. The US was somewhat dependent on Russia's resistance to become the air and nuclear strategic arm of Pejing's violent anti-American activities in the Far East. The emerging picture is that the US, in parallel with the Berlin and Cuba crises (1958–62), wanted to concert the superpowers' activities in China's *'hinterland'* (former 'Indochina') in the sense that both exert pressure on the parties to a conflict amenable to their respective influence and through such agreement attain the neutralization of the conflict area, including the installment of all-party or power-sharing coalition governments, however unstable (Nelson, 1995).

European Perspectives on the Cold War

A different strand in the history of the concept is the perception of the impact of the other Western powers, especially Britain and France, on how the struggle was waged (Greenwood, 2000; Bozo, 1991). The contribution is twofold: (1) the *Cold War* is viewed as a new stage in great power rivalry. These studies stress the Europeans' interest in devoting resources to restoring or preserving their assets and commitments overseas (Kent, 1993; Bossuat, 1992). (2) The second contribution takes a different direction: it challenges the assumption that Western Europe by 1947–48 was in such a critical state that the leading nations had to 'invite' the US to reconstruct and protect Western Europe. Examining the economic potential of the European nations and how their governments used the financial means provided under the Marshall Plan, Milward (1984) presents the thesis of the rescue of the nation-state. His complex argument also draws on the observation that at that time the West did not reckon with an immediate Soviet threat. The implication is that an unwarranted haste was imposed on a process which in any case depended on what the European countries did to and for another, formally, US assistance was tied to the Uniting of (Western) Europe and to parallel bilateral agreements between the US and the recipient country.

Competitive Cooperation between the Superpowers

By the end of the 1960s, researchers discerned the convergence of five developments that demonstrated the continuing relevance of the 'competitive cooperation' between the superpowers for the changing structures of the *Cold War*:

1. Soviet policy shifted toward accepting the US's and Canada's presence in Germany
2. German *Ostpolitik* presumed the engagement of the US in NATO
3. de Gaulle realized in the context of the Prague, 1968 crisis – 'Prague' refers to the invasion of Warsaw Pact troops into Czechoslovakia on 20–21 August 1968 and the arrest of party leader Dubcek, who initiated domestic reforms ("Prague spring" – "Prager Frühling") – that Breshnev's Russia was no party to his vision that dissolving Cold War structures in the West, i.e., France's disengagement from NATO's military organization, might induce 'Russia' to allow for more evolution of national Communist and then independent states in Eastern Europe
4. The US embroilment in the Vietnam War caused a change in the intellectual climate; the abuse of the USSR being the cause of every evil became obsolete; instead the US became the villain in the piece
5. New developments in arms technology – e.g., high-precision weaponry as a substitute for atomic weapons, MIRV-technique (multiple independently targetable reentry vehicles), antiballistic missiles – were beyond Britain's and France's capability to follow on; this reinforced NATO Europe's self-elected dependency on the US with respect to security and defense (Hanrieder, 1989).

Renewed US pressures on its allies to extend their conventional military capabilities and share the burdens for the 'Defense of the West' more evenly, the reescalation of the strategic arms race between the superpowers under the aegis of limitation treaties, and the evidence presented by German *Ostpolitik* that negotiations with Russia generate tolerable results, combined to raise the basic questions: What are the costs of the ongoing *Cold War*? On what terms could the conflict be ended and converted into politicoeconomic competition? (Garthoff, 1985).

From the Second Cold War to the End of the Cold War

The USSR, after getting Germany's pledge to observe the invulnerability of the territorial status quo in Europe, revived the global contest with the US, which was immersed in domestic turbulences *and* disputes with all its allies about oil and the dollar. The Kremlin demonstrated its self-confidence by expanding Soviet naval forces and establishing bases, however short-lived, stretching from Vietnam via Mozambique, Somalia, and Angola to Central America. In contrast to the 1950–53 period, the US catchword 'arch of crises' did not resonate well with its allies. The latter wanted to develop *détente*, notwithstanding the fear, expressed by German Chancellor Helmut Schmidt in 1977, that the Soviets' new equipment (Backfire bombers; SS-20) made NATO-Europe hostage to the Kremlin's whip of the will. This raised the question whether the USSR was about to win the Cold War or whether the Kremlin was overstretching the country's resources and would thus expose the USSR sooner rather than later to the need for radical changes in her system. The wishful thinking that the USSR would fall victim to its inability of continuous adaptation worked out after three decades of aspiring military strategic and political parity with the US. Some authors argue that Reagan's defense buildup deliberately forced the Soviet leadership to acknowledge the failure of its domestic system and hence the USSR's inability to persist in the contest and sustain bipolarity (Adomeit, 1998; Gaddis, 1987; Wells' article in Hogan, 1992). The way the global contest ended invited Americans to believe that they had won the Cold War. By contrast, Garthoff and Lebov/Stein argue that only a Soviet leader could have ended the Cold War, "and Gorbachev set out

deliberately to do so." His initiatives in dismantling the Soviet command (military–industrial) economy and emphasizing 'common security' jettisoned the USSR's Cold War apparatus.

Methodological Problems

The immersion of the concept *Cold War* in the perpetual clash of interests between East and West and within each 'bloc' subjects the researcher on the one hand to the political climate of his own times, and may thus reload or de-emphasize the contentions of the past; on the other hand, access to newly available records reveals new insights into previous phases of the Cold War and thus demands rethinking the past but in a different way. Getting the balance right between these two operations is difficult when knowledge about one party to the conflict is the result of generations of research, whereas the more recent presentations of findings from Soviet, GDR, Czech, or Polish sources are both less systematic or structured and more exposed to be taken instantly as evidence for one interpretation, e.g., of Stalin's or Krushchev's reasonableness, or another, appraising both their internal and external actions and rhetoric. The task to study the records comprehensively, but also be prepared to modify one's assessments in response to newly available empirical evidence is prone to collide with the other obligation, namely to explain what were the basic causes of a conflict and which causes – meaning in politics: sins of commission and omission – are accountable for what developments.

A second main problem is the exact phase-by-phase and overall intersection between the interpretation of the collaboration leading to the evolution of 'Western' structures in the international economy and the assessment of the concomitant events in the politicostrategic (military) sphere, where the USSR appeared to be the winner, but then ended the Cold War on Western terms.

Future Direction of Research

'East' and 'West' waged the struggle by all means and methods except 'hot' war in the area stretching from Vancouver to Wladivostok. Hence, research must attend to different subject areas and to the expertise developed in the many scholarly communities. Some areas of research, e.g., diplomatic or intellectual history and biography, are more established than others. The impact of *intelligence* on policymakers is a relatively new area of systematic research. International cooperation projects have done much to promote *nuclear history* and *strategic studies*, but the history of the military alliances and of national defense organizations and policies depend still on the authorities' grant of access as well as clearance and permission for publishing inspected material. The studied ambiguity of the political leaderships and the top military echelon about the worth of strategic nuclear weapons in case deterrence should fail and about the use of short-range atomic weapons deserves further study in order to know the implications of nuclear weaponry on the conduct of Cold War diplomacy and governmental guidance to their military.

Future research should be more systematic in the sense of *extending* the conceptualization beyond the national and bilateral focus to the regional context and *intensifying* the approach by addressing the fundamental questions about the changing nature of the struggle, its costs, the persistence or recreation of patterns of conflict, and above all the question whether the Cold War structure affected all other bilateral or intraregional conflicts or whether reemerging older conflicts pervaded the East–West conflict, so that the parties to such conflicts used the *Cold War* for the purpose of engaging wealthy allies on their side.

Abstract

James S. Coleman, born on 12 May 1926 in Bedford, Indiana, was among the most important American sociologists of his generation. Coleman was unique among sociologists by importantly influencing both intellectual and policy debate, especially educational policy. He made lasting contributions to several areas of scholarly concern, including our understanding of school effects on learning, the development of rational choice theory in sociology, and the use of mathematics as a tool for the development of theory in sociology. James S. Coleman died on 25 March 1995 in Chicago, Illinois.

James S. Coleman was born on 12 May 1926 in Bedford, Indiana. He died on 25 March 1995 in Chicago, Illinois. Coleman was among the most important American sociologists of his generation. By importantly influencing both intellectual and policy debate, Coleman was unique among sociologists. By making important contributions to a large range of areas of scholarly concern, including mathematical sociology, sociology of education, and social theory, Coleman was unique among social scientists.

Life

James Samuel Coleman was born into a family of teachers, with roots in the landed gentry of the South on his father's side, and in various places in the MidWest on his mother's side. His grandfather, Samuel, was a minister. The family moved frequently in Coleman's youth between places in Ohio, Arkansas, and Kentucky to settle, finally, in Louisville, Kentucky, where Coleman graduated from Manual High School in 1941. The origin is important for his basic sociological interests and positions. The marginality from moving around between southern and northern American cultures and the diversity of his origins instilled a strong curiosity about social relations. The teacher occupations of both parents created a strong interest in schools and education. Samuel, the minister grandfather, and the mother were important for Coleman's preoccupation with moral issues that profoundly influenced his work.

Coleman's choice of sociology as a vocation came quite late. He graduated from Purdue University in 1949, with a degree in Chemical Engineering, and his first job was as a chemist with Eastman Kodak. He had almost no undergraduate education in any social science. Nonetheless, in 1951 he began graduate study in sociology at Columbia University. Coleman's dual attraction to science and moral engagement made sociology an impeccable choice, or so it would seem in 1951. He had found industry frustrating and a likely eventual career in management unappealing. He wanted to devote his life to discovery and concluded it could only be about people, their relationships, and their social organization.

Columbia's sociology department gave Coleman four intense years and three important teachers: Paul Lazarsfeld, Robert Merton, and Seymour Martin Lipset. Coleman is usually regarded as Paul Lazarsfeld's student. This is not quite correct. Lazarsfeld was not his dissertation advisor; it was Lipset. Lazarsfeld was not the teacher who had the most profound intellectual influence on Coleman; it was Merton. Lazarsfeld did involve and use Coleman for the development of mathematical and statistical tools for social analysis, and these activities created the point of departure for some of Coleman's most important later work. However, there is an important difference between Coleman's *Introduction to Mathematical Sociology* (1964) and Lazarsfeld's branch of mathematical thinking in the social sciences. Coleman's main objective with the use of mathematics was the development of theoretical insights and conceptual development. Lazarsfeld's major contributions were to the codification of research procedures, that is, methodology. Coleman has made important contributions to methods, but his most remarkable quality as a sociologist was his ability to develop sociological ideas and sustain them with empirical evidence. This is much closer to Merton's style of theorizing about empirical matters, though Merton often relied on evidence produced by others.

Coleman obtained his first faculty position in 1956 as an Assistant Professor at the University of Chicago. In 1959 he moved to Johns Hopkins University to create his own sociology department. He developed a small organization with an intellectual intensity and excitement that was truly remarkable. It was perhaps unsustainable and, for a variety of reasons, Coleman went back to the University of Chicago in 1973, now as a University Professor, and stayed there until his death in 1995.

Scholarship

The body of scholarly work is large. It includes 30 books and monographs and more than 300 articles and chapters in books. These contributions have profoundly influenced and, in several cases, defined the agenda for important subfields of sociology: sociological theory, sociology of education, sociology of the family, mass-communication, social stratification, political sociology, mathematical sociology, and sociological methods. The contributions include three major pieces of policy-oriented research on schools and educational opportunities that are the major examples of 'sociology making a difference' in the 1960s, 1970s, and 1980s. The scholarly work covers a phenomenal range of approaches to social research. There is work about social systems (Coleman, 1961) and about individual behavior (Coleman, 1990b). There is basic research as well as applied. There is quantitative (Coleman et al., 1966;

Coleman, 1987) as well as qualitative analysis (Coleman, 1961). There are contributions to economics (Coleman, 1966), political theory (Coleman, 1982), moral philosophy (Coleman, 1974), statistics and probability theory (Coleman, 1981), and education (Coleman, 1990a).

It is difficult to characterize James Coleman's contributions to the discipline because there are so many components. It includes two major and two very different paradigms of what sociology is about. One is a Durkheimian paradigm: it sees the task as studying how social structure creates and constrains individual action and causal social processes. The other paradigm takes departure in individual purposeful action for developing properties of social systems and structures. The former project governs most of Coleman's empirical work on educational processes and social processes in educational institutions. The latter project, the development of a sociological, rational action theory, moves, so to speak, in the opposite direction. It is theory aimed at understanding social systems themselves, their development, and properties, beginning with a theory of individual action. It occupied most of Coleman's attention in the last years of his life.

Almost all of Coleman's empirical research was about growing up, about schools, and learning and educational opportunity. His first study of schools was a study of adolescent subcultures based on surveys of students in ten high schools in northern Illinois. The report on this research was published in 1961 as *The Adolescent Society* (1961). In the preface, Coleman notes two reasons for undertaking this study. One was his wish to study how schools might be more effective; he states that the study had its origin in 'a deep concern I have had, since my own high school days, with high schools and with... ways to make an adolescent experience with learning more profitable...' (1961, p. viii). The second concern was an interest in different types of social systems and the value systems they reflect. These two interests, in creating effective schools and other social organizations and in the values and cultures of social systems, would guide Coleman's research throughout his life.

The wish to study the effects of high schools on learning did not receive much attention in *The Adolescent Society*, possibly because the empirical evidence Coleman obtained about these effects, and their relationship to status systems, is quite difficult to interpret. *The Adolescent Society* is primarily a study of adolescent subcultures. The policy prescriptions Coleman drew from his analysis were about how to change these subcultures to encourage learning and academic achievement. This would be done by changing the structure of competition so that students would see academic achievement as a collective good, like sports.

The interest in the effects of schools and school social organizations on learning became the main preoccupation of Coleman's educational research for almost four decades. The link between the two concerns was always clear, and the interest in the social systems created in schools re-emerges as the dominant concern again in his latest research. All of his educational research sees the effectiveness of schools related to the social systems created in schools and in the family and community that form the context for the school social systems. Coleman was very much a sociologist of schools.

Coleman performed three major studies of schools and educational processes after *The Adolescent Society*. The first so-called 'Coleman Report' (for a while referred to by many as the Coleman – Campbell report) was a report on the massive *Equality of Educational Opportunity* survey (Coleman et al., 1966). It is probably the largest social science survey research ever undertaken with some 600 000 students surveyed. The Report's main finding was that the instructional facilities and resources, including per pupil expenditures, have small and comparatively insignificant effects on academic achievement relative to the influence of family background. This result created considerable controversy, a controversy that continues today. A very large number of studies have focused on the issue since then. The best of this research has replicated the main conclusion: there is very little relationship between the amount of expenditure on schools and achievement outcomes, net of the family backgrounds of students. Next to family background, the family background of a student's peers, as measured for example by the racial composition of schools, seems most relevant, especially for minorities. This conclusion had an important consequence for American schools as it was used to justify racial desegregation in public schools. The second Coleman Report focused on this effect on policy: the use of busing to integrate schools and reap some of the benefits of desegregation on the academic achievement of minorities. The Report concluded that the policy had been ineffective. This conclusion was widely interpreted as denying the benefits of desegregation documented in the First Report and was strongly attacked by many, including many of Coleman's fellow sociologists. The interpretation was not correct. Coleman did not doubt the relevance of social systems created by student body composition for schools' educational climates. He doubted the long-term benefits of busing as a remedy for segregation because it encouraged white flight from desegregated public schools.

The allegation that Coleman had reversed his position would be repeated with the publications from the third major piece of educational research published in the early 1980s. In a series of publications, for example *Public and Private High Schools* (Coleman and Hoffer, 1987), Coleman and co-authors concluded that Roman Catholic parochial schools produced more learning and superior educational outcomes than public schools because of superior social resources, or social capital created by the involvement of parents with schools and their personnel. These conclusions resulted in another set of published controversies, now about the existence of school effects – the very effects that were said to have been denied by Coleman in the first Report. Now, the tables had been reversed. The critiques now denied the existence of school effects, in particular the apparent superiority of Catholic schools.

Coleman strongly believed in the use of mathematics as a language for the development of social theory. His *Introduction to Mathematical Sociology* (1964) remains unsurpassed as a text on how to use mathematics, in particular stochastic process models, to mirror social processes of diffusion and influence in groups. It is an enormously rich collection of tools for the analysis of social processes. Coleman remained committed to the use of mathematics for the development of theory. Over time, he changed the type of theory focused upon, from modeling the mechanism of social processes in his early work, to modeling the outcomes of purposive action in his later work. Throughout, Coleman's contributions provide perhaps the most important demonstration of the power of mathematics as a tool for social theory in contemporary sociology.

Already in the 1960s, Coleman published several articles on a model for collective decisions where actors trade control over events and resources to maximize their interests. This work came about as a result of Coleman's interest in developing games for learning and for social theory, where players engage in transactions designed to mirror important learning tasks or to simulate basic rules of social systems. One ofthese games was called the legislative game, and was designed to simulate the transactions going on in a legislative body with vote trading. Coleman formalized this game in a simple model that provided equilibrium outcomes providing measures of the power of actors and the value of events. These ideas became the basis for what became his major preoccupation in the 1970s and 1980s: creating a rational action basis for social theory where the emergence of macro social structures are clearly linked to micro foundations.

The outstanding result of many years of effort became *Foundations of Social Theory* (1990). It is a major book in ambition, achievement, and size. It provides theory and theoretical tools for the analysis of existing society and the creation of better societies. The book moves from the analysis of elementary action and social relations of trust and authority to the development of norms and more complex authority systems or corporate actors, such as large corporations, and then on to the analysis of the major institutions of modern society. A major concern for Coleman was the distribution of power in society and the problem of holding corporate actors responsible for their actions. *Foundations of Social Theory* is an unfamiliar contribution to a discipline where theory often seems to be an exegeses about the theory created by those who are safely dead, or abstract conceptual development with little if any empirical reference. This major book aims to shape the discipline by providing a theory and a mathematical structure that may have extraordinary potential for research. The realization of this potential depends not only on the quality of the ideas, but also on the discipline's ability to retool. Some concepts from the book have become prominent in sociology, for example Coleman's ideas about the micro – macro link and about social capital. However, this is only a part of this enormously rich contribution. Coleman knew that an extraordinary educational effort was needed, and he devoted much of his attention to this effort in his last years, for example, by founding and editing the journal *Rationality and Society*.

Coleman's theoretical work created a landmark in social theory. His concern for developing a mathematical language for the analysis of empirical processes created a rich set of tools that eventually may change the way sociologists work. His empirical work often includes imaginative interpretation and brilliant insights. Though his emphasis increasingly was on the project that resulted in *Foundations of Social Theory*, Coleman repeatedly returned to empirical research on causal processes with individual actions and lives as the outcome. The synthesis was accomplished in some of Coleman's latest empirical work, on schools, family, and community.

Impact

There was no lack of recognition of Coleman's scholarly contributions by the bodies that confer the highest prestige upon scientists. Coleman was elected to the American Academy of Arts and Sciences in 1966, the National Academy of Education in 1966, the American Philosophical Society in 1970, the National Academy of Sciences in 1972, and the Royal Swedish Academy of Sciences in 1984. He was a Fellow at the Center for Advanced Study in the Behavioral Sciences, a Guggenheim Fellow, and Fellow at the Wissenschaftskolleg zu Berlin. He received numerous honorary degrees from universities in the USA and Europe.

Despite all the recognition, American sociology had, and still has, considerable ambivalence toward Coleman. His international reputation, particularly in Germany, the Netherlands, and Scandinavia, and his reputation outside of sociology seemed often more solid than his reputation in American sociology. He became President of the American Sociological Association (ASA) from 1991 to 1992, but he never held another elected office in the ASA. His election to the Presidency in 1990 was the result of a write-in campaign and not of a nomination by the Association. Indeed, the leadership of the ASA, including the ASA President, tried to censor him in the mid-1970s for producing subversive sociology, because his work on the impact of busing on white flight threatened traditional liberal beliefs. It was an ignominious act that almost succeeded.

The ambivalence of the profession toward Coleman had two main sources. One was Coleman's unwillingness to specialize in one of the usual three main roles for sociologists: as theorist, methodologist, or researcher. This contradicts the implicit theory most of us have that one cannot be outstanding in all three roles. Coleman was outstanding in all three, but specialists in theory, methods, or research had difficulties recognizing his achievements. The second, and probably major, source of ambivalence was Coleman's use of research to draw policy inferences. Coleman stated what his research meant for policy and was not hesitant to do so when it contradicted conventional wisdom. He loved controversy. Each of the three Coleman Reports stated a conclusion that infuriated many: that school resources have little impact on academic achievement compared to the family resources of a child; that busing to achieve racial integration speeds up the process of white flight from our central cities; that schools organized as many private Roman Catholic schools produce more learning and less inequality in learning than schools organized like the typical public school. In every instance, an army of researchers tried to find fault with the evidence for these conclusions and largely failed. They concentrated on specific statistical issues. This was a mistake when confronting Jim Coleman. He anticipated criticisms by demonstrating the main finding in several ways. Moreover, his powerful intuitions about the mechanisms that create observed outcomes produced coherent arguments that Coleman effectively integrated with empirical analysis, while the opposition failed to formulate an alternative argument that could be sustained with evidence.

Sociology is profoundly influenced by James Coleman. So are many individual lives and careers. None of his students and followers moved with him through all the projects, but remain in one or the other of his many areas of interests. Those who had the privilege to know him were always profoundly touched by his excitement of translating into empirical analysis theoretical ideas about how social structure affects individuals. Coleman's enormous mental (and physical) energy never ceased to amaze. This energy and creativity were sustained by

his certitude about the importance of the project of making sociology a better tool for a better society.

Appraisals of Coleman's scholarly and policy contributions may be found in Sørensen and Spilerman (1993) and Clark (1996). The latter volume, published after Coleman's death, includes a complete bibliography and several autobiographical fragments.

Collaborative Consumption

Abstract

We review a marketing reality borne of the digital era, collaborative consumption, in which individuals actively engage in the production of service offerings for the benefit of others. This phenomenon is rapidly gaining momentum with the advent of new technology and firms that seek to develop profitable business models by leveraging their Web platforms to engender trust among strangers and facilitate transactions among consumers. As a result, collaborative consumption has helped push traditional consumption communities from localized marketplaces with limited economic activity to collaborative global communities with important economic, environmental, and social effects.

Since the widespread adoption of Web 2.0 (2000s) there has been an enormous shift in the ability of consumers to provide services and coproduce consumption experiences for themselves and others. The proliferation of networked technologies has transformed exchanges among individuals, as online and mobile platforms are deployed to equip ordinary people with the ability to monetize their resources and skills. Reduced economic costs, time, and effort required for consumer participation in the production of market offerings has rendered exchange among individuals convenient, easy, and as readily available as Internet access. This phenomenon, which Botsman and Rogers (2010) call collaborative consumption, is rapidly gaining momentum. Collaborative consumption has been featured as one of 10 ideas that will change the world in the coming years (Walsh, 2011).

Collaborative consumption, which was estimated at more than $3.5 billion in 2013 (Geron, 2013), allows revenues to flow directly into individuals' pockets. For example, Konrad Marshall, a journalist, spent a week immersed in collaborative consumption, earning $335 for about 20 h of work that included hauling bricks for a suburban resident building a backyard chicken coop ($50), writing a bio for a band ($80), unpacking boxes and organizing their contents in a new home ($60), and a few other jobs (Marshall, 2014). Similarly, Larson Frederic generated about $3000 income a month renting his home and transforming his Prius into a *de facto* taxi (Geron, 2013). As Konrad and Larson illustrate, collaborative consumption allows individuals to leverage online and mobile platforms to monetize their skills and their idle assets. Such exchanges also operate largely within an informal economy as profits often go unreported and local taxes or fees uncollected.

Background on Collaborative Consumption

Collaborative consumption is also referred to as the 'sharing economy' because individuals are sharing access to resources (for a fee or other compensation), or 'peer-to-peer' exchange because both the service provider and recipient are individuals rather than businesses. Although exchange among individuals has taken place as long as people have been trading, bartering, and swapping, these traditional face-to-face peer exchanges had limited appeal and were restricted by geographic bounds. Moreover, exchange models such as garage sales or swap meets are temporary in nature and people who participate in these exchanges tend to oppose traditional marketplaces (Belk et al., 1988). As such, their attractiveness is limited to a niche market.

With the advent of new technology, however, these traditional consumption communities have evolved from localized marketplaces with limited economic activity to collaborative global communities with significant economic, environmental, and social consequences. Chalmers et al. (2013) analyzed nearly 100 articles published in marketing and consumer research and identified several dimensions on which consumption communities vary. Based on this structural classification, collaborative consumption communities are scalable, nongeographically bound, and enduring platforms that operate synergistically with traditional marketplaces. These new platforms of peer exchange are attractive to a broad market because they bring the convenience and access associated with traditional business-to-consumer practices to consumer-to-consumer exchange.

Beyond technology, what has propelled collaborative consumption practices is the involvement of firms that facilitate exchanges among peers. Older, established firms, such as *Craigslist* and *eBay*, have given way to a wide variety of firms that serve to connect or facilitate peer exchanges. These firms are growing tremendously in number, size, and profits. For example, *Lyft* provides on-demand peer-driven rides in cities across the United States and has recorded more than one million rides since it was founded in 2012 (http://blog.lyft.com); *TaskRabbit*, which outsources household errands and skilled tasks in the United States and the United Kingdom, boasted 1.25 million new users in 2013 alone (http://blog.taskrabbit.com); *thredUP* is a clothing resale platform earning sellers $3.2 million and saving shoppers $21 million in 2013 (http://www.thredup.com/resale); the 1 million members of *Quirky*, a community of inventors who collaborate in developing unique products, have developed over 350 products (https://www.quirky.com/about); and *LendingClub*, a peer-to-peer lending platform, has provided more the $5 billion in total loans, earning investors nearly $500 million in interest as of September 2014 (https://www.lendingclub.com). Indeed, firms and marketers have good reasons to be interested; a 2012 consumer panel survey found that generation X consumers with household incomes exceeding $75 thousand per year find

collaborative consumption most appealing, indicating a healthy market potential (Franz, 2012).

Collaborative consumption markets are structurally different from the traditional buyer-seller dyad; they are triadic, rather than dyadic (Perren et al., 2014). Firms in this market serve as intermediaries between an individual providing a service and the person benefiting from the service. Each actor in this triadic exchange is interdependent and actively involved in the coproduction of a unique consumption experience. Importantly, the roles of the firms, sellers, and consumers can differ across types of markets (e.g., some require buyers to contact sellers directly, in others buyers and sellers have no contact; some firms assume responsibility if a product or service fails, others do not). As such, collaborative consumption markets are more dynamic, flexible, and less institutionalized than traditional markets.

In addition, collaborative consumption markets are challenging existing business models and current regulatory environments. Collaborative consumption has emerged as a viable alternative to traditional business in industries such as transportation, hospitality, retail, and banking. As the popularity of these practices has grown, so has its economic, environmental, and societal impact. Recently, discussion of collaborative consumption has risen to the level of heated debate, along with increased attention from legal and regulatory bodies. Some collaborative practices have been deemed illegal (e.g., short-term rentals are prohibited in cities like New York and San Francisco) and lack of regulation and oversight of these informal transactions in areas traditionally regulated such as food preparation, banking, or transportation could expose collaborative consumers to risks.

Although collaborative consumption has gained the most popularity in wealthy countries like the United States, the United Kingdom, and Australia, developing nations are also embracing these new business models. Moreover, developing economies have a great potential to benefit from collaborative practices to alleviate lack of access to resources. Firms like *Airbnb* and *Uber* have already entered markets in Latin America, Asia, the Middle East, and Africa, while local entrepreneurs have sprung-up businesses to tackle problems such as access to education and financing.

Collaborative Consumption and the Evolution of Consumer Roles

Marketing research has documented the evolution of consumer roles in market exchanges. Service marketing scholars recognized the participatory role of the customer in value creation by highlighting the importance of 'partial employees' in the conceptualization of service quality (Kelley et al., 1990), as well as the value of 'commercial friendships' in interpersonal exchange between customers and service providers (Price and Arnould, 1999). Consumers' helpful, discretionary behaviors were conceptualized as 'customer voluntary performance' (Bettencourt, 1997), and later as 'customer citizen behaviors' (Rosenbaum and Massiah, 2007). A second rich body of literature in consumer research centered on the concept of 'brand community' (Muniz and O'Guinn, 2001) recognized that individuals can be an important information source for other individuals, providing social benefits and representing a form of consumer agency (Schau et al., 2009). Finally, scholars have recently attempted to subsume many of the behavioral manifestations toward a brand or firm under the concept of 'customer engagement behavior' (VanDoorn et al., 2010).

None of these conceptualizations captures the full extent of activities involving individuals in collaborative consumption, however. For example, partial employee, customer voluntary performance, and customer citizen behaviors are conceptualized in the context of consumer receiving a service from a firm, not being the service provider themselves. Similarly, customer engagement behaviors are theorized as customers' behavioral manifestation toward a brand or firm *beyond purchase* but don't necessarily address the service provider role that customers adopt in collaborative consumption. Collaborative consumption challenges all these traditional views of consumers (Vargo and Lusch, 2004) and point to a new stage in the evolution of the consumer role.

Likewise, this evolution of consumers from passive recipients of goods and services produced by businesses to active participants working collaboratively with enterprise in the marketplace is underscored by the proliferation of literature in sociology and consumer culture literature advocating its significance as well as criticizing its merits. Consumer culture theorists in particular have critically examined the marketing discourse and worklike activities carried out by consumers (Ritzer and Jurgenson, 2010; Dujarier, forthcoming; Cova and Cova, 2012; Zwick et al., 2008). Nonetheless, the concepts of 'prosumer' and 'prosumption' have become central to understanding the growing role of collaborative practices in shaping economic relations in contemporary capitalist society (Comor, 2010; Denegri-Knott and Zwick, 2011; Ritzer et al., 2012).

Differentiating Collaborative Consumption from Other Online Collectives

Collaborative consumption marketplaces where people coordinate the acquisition and distribution of a resource in exchange for a fee or other compensation (Belk, 2014) can be differentiated from other consumption communities studied in marketing and consumer behavior literature. **Table 1** provides a summary of the similarities and differences among key online collectives. First, brand communities such as online groups for Star Trek fans (Kozinets, 2001), are virtual meeting spaces where individuals can connect with each other to share experiences and advice; these groups focus on a central brand or product and foster a sense of collective belonging (Muniz and O'Guinn, 2001). Second, collective innovation communities refer to collaborative platforms where collective participatory actions of online consumers give rise to creativity and innovation (Kozinets et al., 2008). Similarly, virtual peer-to-peer problem solving communities focus on collaborative problem-solving activities related to consumption experiences of any type (Mathwick et al., 2008). The latter two online collectives provide a space for consumers to collaborate, innovate, and problem solve. Third, digital content sharing communities focus on sharing of digital 'e-goods' distributed for free among peers (Plouffe, 2008). Web sites such as Kazaa and Napster provide a meeting space to share digital content.

Table 1 Differences and similarities among online collectives

	Collaborative consumption	*Brand communities*	*Collective innovation communities*	*Digital content sharing communities*
Definition	Market model that enables individuals to coordinate the acquisition and distribution of a resource for a fee or other compensation (Belk, 2014), where the interaction is at least partially supported or mediated by technology	Specialized, nongeographically bound community, based on a structured set of social relationships among admirers of a brand. At its center is a branded good or service and it is marked by a shared consciousness, rituals and traditions, and a sense of moral responsibility (Muniz and O'Guinn, 2001)	Online creative consumer communities are collaborative platforms where collective, participatory actions of online consumers give rise to innovation (Kozinets et al., 2008). Peer-to-peer problem solving communities are networks of practice where consumers are 'working' to solve problems related to their shared consumption experiences (Mathwick et al., 2008)	Sometimes called P2P systems or P2P networks. Described as a form of exchange between individual consumers who operate in conjunction with one another, all outside the realm of traditional channels and the value chain, broadly construed (Plouffe, 2008)
Prototypes	Craiglist, ebay, Airbnb, Lending Club, Lyft, Uber	Ford Bronco, Macintosh and Saab online communities Star Trek fan communities	Flickr, Wikipedia, Crash the Super Bowl Lonely Planet's Thorn Tree Forum and VirtualTourist.com	Digital downloading Web sites such as Kazaa, Napster, Morpheus, and AudioGalaxy
Community purpose	Alternative marketplace to exchange of goods/services	Virtual meeting space to connect with others, share experiences, and advice	Virtual space to collaborate, innovate, or receive consumption problem solving advice	Virtual meeting space to share digital content
Type of activity	Commodity exchange	Sharing	Sharing	Sharing
Economic activity	Underground economy (often taxes are not paid, income goes unreported)	N/A – no economic activity takes place	N/A – no economic activity takes place	Illegal economic activities (often users do not have rights to distribute downloaded music)
Characteristics (*based on* Chalmers et al. (2013) *structural classification of consumption communities*)	● Can be online or both online and face-to-face ● Appeal can vary from limited to broad ● Focused on consumption activity ● Easy access ● Heterogeneous participants	● Online ● Appeal can vary from limited to broad ● Focused on a brand ● Access can vary from easy to limited ● Homogenous participants	● Online ● Appeal can vary from limited to broad ● Can be focused on brand or consumption activity ● Access can vary from easy to limited ● Homogenous participants	● Online ● Broad appeal ● Focused on consumption activity ● Easy access ● Heterogeneous participants
Service provider role	Varying roles depending on the extent to which it facilitates the exchanges	N/A – not involved	N/A – not involved	Provides platform for exchange
Key differences from collaborative consumption		● Sense of collective belonging ● Built around brand loyalty ● Not an exchange/marketplace	● Sense of collective belonging ● Built around shared desire to solve consumption-related problems ● Not an exchange/marketplace	● Not a marketplace ● Participants do not derive income from activities

Collaborative consumption communities differ from brand communities, collective innovation communities, and digital content sharing communities in three key aspects: community purpose, type of consumption activity, and type of economic activity. Collaborative consumption communities are formed with the explicit purpose of facilitating economic exchange of goods and services among individuals and rarely have a brand-specific focus. In contrast, the aforementioned communities have more prosocial purposes and their members engage in noneconomic activities such as sharing experiences, advice, or digital content.

The Effects of Collaborative Consumption

The effects of collaborative consumption can be felt at multiple levels, including the environment, the economy, individual consumer, and society at large. Consider, for example, potential effect on the environment. Marketing scholars argue that consumption turns into problematic behaviors – overconsumption – when the level of consumption becomes unacceptable due to environmental consequences, unaffordable due to economic consequences, or when it negatively affects personal and collective well-being (Sheth et al., 2010). Participation in collaborative consumption mitigates overconsumption by altering the consumption cycle and allowing individuals to acquire, use, and dispose of their assets in a way that positively influences the three pillars of sustainability: environmental, economic, and social (Huang and Rust, 2011). Environmental benefits are realized by extracting more use from assets that would otherwise go unused. For example, most power tools are used less than 13 min in their lifetime (Botsman and Rogers, 2010); when consumers are enabled to rent out or sell a tool to other consumers, the environmental impact can be minimized while maximizing its utility during the product's lifespan. In short, collaborative consumption potentially results in more sustainable consumption behaviors that benefit individual consumers, businesses, and society (Botsman and Rogers, 2010).

Collaborative consumption has also had a major economic effect on traditional markets, disrupting existing institutions in key industries like transportation, hospitality, and banking. For example, hotels lost revenue from the 9 million guests who used *Airbnb*, banks failed to collect interest from the $5 billion loans funded through *Lending Club*, and taxi and car rental companies lost millions of customers thanks to *Uber*, *Lyft*, and other ride-sharing businesses. Zervas et al. (2014) did find that *Airbnb* penetration into the state of Texas was negatively correlated with hotel revenues, with lower-end hotels and those with little conference space incurring the most financial cost. Their model projects that in the state of Texas, a 1% increase in the market size of *Airbnb* will result in 0.05% decrease in total hotel revenues. In short, collaborative consumption represents an important societal shift by altering the traditional exchange between consumers and firms, requiring even well-established markets to adapt their existing practices or marketing strategies.

Significant effects can also be seen at the individual level. Collaborative consumption may serve as a platform upon which individuals can enact and reinforce their political and personal ideologies. For example, proponents of collaborative consumption view it as a prosocial consumerist movement whereby individuals engage in political consumerism, using conscious consumption as a political tool (Parsons, 2014). Since these exchanges are less costly than traditional marketplaces, individual consumers benefit economically by fulfilling consumption needs at lower costs. The consumer providing the product or service also benefits from receiving supplementary income (as does the business facilitating the exchange). These marketplaces may also enhance social and individual well-being by strengthening a sense of community as consumers collaborate with each other. Yet, recent findings suggest that this may not always be the case. In a case study of car sharing conducted in Boston, Massachusetts, Bardhi and Eckhardt (2012) found that *Zipcar* users do not have an interest in meeting and socializing with other member despite the company's efforts to foster a sense of community. Others have noted that relationships with neighbors may be strained as individuals rent out their homes to strangers who may not ascribe to community norms of noise or cleanliness, disrupting the process of community building and sense of safety among local residents (Zervas et al., 2014).

There is little doubt that collaborative consumption will continue to have an important effect on society and that firms participating in these exchanges will continue to grow. Start-ups such as *Airbnb* and *Lyft* have raised $130 and $83 million respectively, in venture capital funding (Owyang, 2013). Similarly, *Lending Club* received $57 million from investors in 2013, placing the company's valuation at $2.3 billion and creating anticipation about going public in 2014 (Calvey, 2013). Most recently, *Uber* raised $1.2 billion in a round of funding with a valuation of over $18 billion, making the 5-year-old San Francisco start-up more valuable than companies such as Whole Foods and United Airlines (Knowledge@Wharton, 2014).

Future Research Directions

Despite its importance, scholarly research investigating this consumption phenomenon remains scant (Prothero et al., 2011), and the implications for firms, individuals, and societies are not well understood. Research is needed to understand the structure of collaborative consumption markets. What role do consumers and firms play within this market? What 'logics' dominate? How are various collaborative consumption markets similar or different from one another? Answers to such questions would provide practical guidelines for service marketers and help develop theory to advance theoretical understanding of the collaborative consumption phenomenon. Collaborative consumption communities also are fertile grounds for academic research to examine the evolving role of consumers as coproducers of their consumption practices and the strategies organizations deploy to harness its power. In terms of sustainable consumption, Prothero et al. (2011) argue that the full consumption cycle needs to be further investigated, as individuals' postpurchase behaviors (e.g., product usage, product life extension, and disposal) all have significant effects on the sustainability of consumption. Thus, how does the increased adoption of collaborative consumption markets affect sustainability? At the same time, alternative outlets that

allow consumers to alter how they use and dispose of their belongings could have important consequences for nonprofit organizations that rely on donations.

Participation in these marketplaces could enable individuals to pursue independent business opportunities instead of traditional employment, creating a new wave of micro-entrepreneurs. Research is needed to investigate whether collaborative consumption gives rise to new forms of consumer agency and how that shapes the labor force. Moreover, the regulatory environment remains in flux, and both firms and lawmakers could benefit from quality research that sheds light on the role of laws and regulation in assisting or inhibiting the growth of these business practice. For example, how can research better assess the effect of the largely informal economy, including the income that probably goes unreported? What are the consequences for local governments as sales and service taxation goes uncollected? Some evidence has surfaced to suggest that the total impact of collaborative consumption activities could be more positive than expected. A report commissioned by *Airbnb* claims that the company contributed an estimated $56 million to San Francisco's economic activity in the period from June 2011 to May 2012, providing locals with substantial income and having a positive effect on local neighborhoods that are 'off the beaten path' (Triple Pundit, 2013). However, more extensive independent studies are needed in order to measure and assess the real effects of this collaborative economy.

Organizational, legal, and community-level questions and concerns also arise. What effect will collaborative consumption have on organizations? For the collaborative consumption firms themselves, there are unique challenges such as how to contend with the complexities of serving two separate parties in the exchange and manage the increasingly volatile regulatory environment. More generally, will certain businesses be better able than others to integrate collaborative consumption models into their existing platforms and thereby tap into these lucrative markets? If so, will collaborative consumption be co-opted by more powerful markets (e.g., *Avis* acquired *Zipcar* in 2013)? The power struggle between emerging collaborative consumption markets and more established, traditional ones, is already being played out in a number of communities. For example, in 2012 the California Public Utilities Commission issued fines against car-sharing firms (*Lyft*, *SideCar*, *Uber*), yet American Express card members can now use their reward points for rides through *Uber*. Even organizations unrelated to the collaborative consumption movement may find themselves struggling with the realities of networked peer platforms. The University of California (UC) system found itself in the middle of a media storm when its director of travel services sent a message to faculty members warning them not to use the new peer-to-peer or sharing businesses such as *Uber*, *Lyft*, and *Airbnb* when traveling on UC business because "these services are not fully regulated and do not protect users to the same extent as commercially regulated business" (N.B., 2014). After the California lieutenant governor sent a letter urging university officials to reconsider such policy, UC's office of travel services issued a retracting statement.

For individual consumers, we might ask how and when does participation in collaborative consumption shape or change identities? There is an inherent incompatibility between prosocial values and the self-serving benefits linked to collaborative consumption. Does increased participation diminish the importance of moral identity, and thus weaken associated values and motives? Amid the aftermath of the global financial crisis during the 2000s, a heated debate has been brewing in the popular press about the nature of collaborative consumption practices, questioning whether the so-called 'sharing economy' is a manifestation of the empowered and entrepreneurial consumer or just the latest form of contemporary capitalist exploitation. The dualism between individual voluntaristic action and constrained deterministic behavior echoed in this contemporary discourse has long been at the center of scholarly debate regarding the primacy of structure or agency in shaping human behavior. Yet we know little about how peers experience these coproduction practices or how they perhaps construct entrepreneurial identities as a way of negotiating key tensions in this structure–agency dichotomy. Moreover, prior research investigating interactions among consumers surrounding marketer generated word-of-mouth campaigns suggest that the "intrusion of commercial 'hype' presents a type of moral hazard when it contains the inappropriate and unsanctioned mixing of dominant norms, such as sharing, caring or market exchange" (Kozinets et al., 2010: p. 85). Thus, consumer research is needed to determine if and how tensions arise due to both the social and commercial nature of exchange between peers. For example, how does monetary versus nonmonetary compensation affect exchange behaviors in collaborative consumption markets? What are the antecedents necessary to develop trust in other peers? And what effect does collaborative consumption have on interpersonal relationships, including neighbors?

What is needed is a broad research approach that includes different levels of analyses (structural, organizational, and individual) to understand how social structures, market institutions, and consumer practices interact to generate, maintain, and enforce a social order that combines the social domain of peers with the economic domain of market exchange. Such an approach could advance theoretical understanding of the collaborative consumption phenomenon and provide practical implications for managerial practice, public policy, and communities.

Collective Action

Bert Klandermans, VU University, Amsterdam, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by A.R. Oberschall, volume 1, pp. 49–54, © 2001, Elsevier Ltd.

The article answers the questions of what is collective action, why do people participate in collective action, and how is preparedness to participate turned into action? As most collective action concerns acts of political protest, I concentrate on collective political action. Three motives are distinguished: instrumentality referring to participation as an attempt to influence one's situation; identity referring to participation as an expression of group identification; and ideology referring to participation as an expression of one's views. Anger strengthens motives to participate and increase the likelihood that motivation turns into action. Social embeddedness is crucial in the transformation of readiness into action.

Protests in the 'new' democracies in Central Europe about 'stolen elections', street demonstrations in the 'old' democracies against austerity measures, ongoing protests in the Arab world for more democracy, and occupied city squares throughout the world to rally against inequality and to claim better governance. Men and women of all ages express their grievances and aversion. They are mobilized through the media, through organizations they are members of, or by people they know. They come alone, or with family or friends. This article is about collective political action, that is to say, collective action aiming to influence politics. Almost daily our news media report on how people try to influence politics by collective action. This is not to say that political protest is something people regularly do. In fact, participants in political protest are most of the time a minority. Even mass mobilization rarely encompasses more than a few percent points of the population. This raises a question that has always occupied students of collective political action, especially social and political psychologists: *Why do some individuals participate in collective action while others do not?*

What Is Collective Political Action?

Collective political actions are challenges by people with common purposes and solidarity in interaction with elites and authorities (Tarrow, 1998: p. 4).

This definition includes two key elements that deserve some elaboration. First, collective political actions are *challenges*. They concern disruptive direct action against elites, authorities, other groups, or cultural codes. There is an obvious reason why this is the case. Collective political action is typically staged by people who lack access to politics. Had they had access there would have been no need for the action. Disruption forces authorities to pay attention to the claims brought forward. Second, it concerns people with a common purpose and solidarity. Participants rally behind common claims; they want authorities to do something, to change a state of affair or to undo changes. Such common claims are rooted in feelings of collective identity and solidarity. If these challenges gain sustainability, they constitute a social movement.

At the same time, a decline of participation in party politics is reported (Dalton and Wattenberg, 2000). Some labeled this trend 'movimentization of politics' (Neidhardt and Rucht, 1993), while others coined the term 'movement society' (Meyer and Tarrow, 1998; Johnston, 2011). Some facts: for example, in 1975, 22% of the British people signed some petition. In 1990, the figure was 75%. In 1974, 9% of the British participated in a demonstration against 25% in 1990. Between 1979 and 1993, the number of protest events in the French city of Marseille more than doubled from 183 to 395 events per annum. In that same period, considerable increases in protest events in Germany were reported, a result that is confirmed by Kriesi, Koopmans, Duyvendak, and Giugni's now classical study on new social movements in Europe (1995). According to the European Values Surveys, between 1981 and 2008, the proportion of the French population declaring they had at some time or another actually signed a petition, has climbed from 43 to 64%, as has participation in a lawful demonstration (25–42%), or a boycott (10–16%). Finally and somehow against the observed trend, the five rounds of the European Social Survey between 2002 and 2010 reveal a fairly stable 6–7% of the population of 16 European countries reporting participation in lawful demonstration in the past 12 months; 25–26% signed a petition, while 17–18% boycotted some products.

Why Do People Participate in Collective Political Action?

The social psychology of protest suggests that three fundamental motives plus anger account for participation in collective political action (van Stekelenburg and Klandermans, 2007): people may want to change their circumstances, they may want to act as members of their group, they may want to express their views, or they may want to vent their anger. I suggest that together these four factors account for most of the participation in collective political action. I refer to the three motives as: instrumentality, identity, and ideology. *Instrumentality* refers to participation as an attempt to influence one's social and political situation; *identity* refers to participation as an expression of identification with a group; and *ideology* refers to participation as an expression of one's views. *Anger* amplifies and accelerates; it strengthens motives to participate and makes it more likely that motivation turns into action. I hold that approaches that neglect any of those factors are fundamentally flawed. To be sure, individual participants may participate because of a single motive, but all three plus anger are needed

to understand why people take part in collective political action.

The Motivation to Participate in Collective Political Action

Instrumentality

Instrumentality begins with grievances (Klandermans, 1997), be it the experience of illegitimate inequality, feelings of relative deprivation, feelings of injustice, moral indignation about some state of affairs, or a so-called suddenly imposed grievance (an event imposed on people, for example, austerity measures taken by government). Social psychological grievance theories such as relative deprivation theory, or social justice theory have tried to specify how and why grievances develop. Resource mobilization theory and political process theory, the two approaches that dominate the field since those days, have always taken as their point of departure that grievances are ubiquitous and that the key question in action participation research is not so much whether people who participate are aggrieved, but whether aggrieved people participate. The instrumentality paradigm holds that participants are people who believe that they can change their social and political situation at affordable costs.

The perceived costs and benefits of collective action can be distinguished in *selective* and *collective* incentives (Klandermans, 1997). Selective incentives relate to costs and benefits that differentiate between participants and nonparticipants. You are only spending time or money if you participate; you only run the risk of being beaten up by the police if you participate; your friends will only blame you for not participating if you stay home, and so on. Sometimes movement organizations try to make participation more attractive by providing selective benefits: a popular music group, a train ticket to the city where the demonstration is held, a T-shirt, etc. Authorities or opponents on their part can try to make participation less attractive by imposing costs upon participants. Collective incentives are related to achievement of the movement's goals and the extent to which participation in a specific activity contributes to goal achievement. Obviously, it is not enough for a goal to be important to a person, some likelihood of success is also needed (Corcoran et al., 2011). The problem with collective action is that it is difficult to know to what extent an activity will have any influence on authorities. In any event, chances are low that an activity will have any impact if only a few people participate. Therefore, the likelihood of success is influenced by the expected behavior of others (Klandermans, 1984). If too few people participate it is unlikely that the activity will make any difference. As a consequence, expectations about the behavior of others play an important role in the decision to participate. If someone expects that only a few people participate his or her motivation to participate will be low. In a way, the expectation about other people's behavior functions as a self-fulfilling prophecy: if people believe that only few will participate, they will not be motivated to participate and thus make their own expectation true.

Instrumentality presupposes an effective movement that is able to enforce some wanted changes or at least to mobilize substantial support. Making an objective assessment of a movement's impact is not an easy task, but movement organizations will try to convey the impression of an effective political force. They can do so by pointing to the impact they have had in the past, or to the powerful allies they have. Of course, they may lack all this, but then, they might be able to show other signs of movement strength. A movement may command a large constituency as witnessed by turnout on demonstrations, or by membership figures, or large donations. It may comprise strong organizations with charismatic leaders who have gained respect, and so on. Instrumentality also implies the provision of selective incentives. Movements may vary considerably in the selective incentives for participation they provide. This is, obviously, also a matter of the resources a movement commands. Surprisingly little comparative information is available on the resources movements have at their disposal. In a similar vein, systematic documentation is lacking on the way in which the larger political system and the alliances and opponents of movement organizations influence movement participation. It was Tilly, who in 1978 coined the now classic terms 'repression' and 'facilitation' to distinguish between political systems that increase or decrease the costs of participation. Indeed, repressive political environments may increase the costs of participation considerably: people may lose friends, they may risk their jobs, or otherwise jeopardize their sources of income, they may be jailed, and they may even lose their lives.

From an instrumental perspective, a solution must be found to the dilemma of collective action. In 1965, Mancur Olson published his *The Logic of Collective Action*. The core of the book is the argument that rational actors will *not* contribute to the production of a collective good unless selective incentives persuade them to do so. Collective goods are characterized by 'jointness of supply'. That is to say, if they are made available to one person, they become available to everybody irrespective of whether people have contributed to the production of the collective good (for example, a law against discrimination, or measures against pollution). Therefore, according to Olson, a rational actor will choose to take a free ride, unless selective incentives prevent him from doing so. Olson's argument was soon applied to social movement participation. It helped to explain why so often people do not participate in social movements, despite the interest they have in the achievement of the movement's goals. Movement scholars argued that movement goals typically are collective goods. If the goal is achieved people will enjoy the benefits irrespective of whether they have participated in the effort. In view of a goal for which achievement is uncertain, but for which benefits – if materialized – can be reaped anyway, rational actors will take a free ride.

However, social movement scholars quickly discovered that reality was more complex than Olson's simple model suggested. The problem with Olson's logic of collective action is that it provides an explanation for why people do not participate, but fares poorly in explaining why people *do* participate. Moreover, Olson's solution that people participate for selective incentives is fundamentally flawed, as it does not give a satisfactory answer to the question of where the resources needed to provide selective incentives come from (Oliver, 1980). If these must be collected from individual citizens the same collective action dilemma arises again. This is not to say that selective incentives are irrelevant, but that in the final instance they cannot solve the collective action dilemma. In other words, if

collective and selective incentives do not provide a sufficient explanation of movement participation, what else might make the difference? A recurring criticism was that Olson's model assumes that individuals make their decisions in isolation, as if there are no other people with whom they consult, with whom they feel solidarity, and by whom they are kept to their promises. This pointed to the significance of collective identity as a factor in movement participation.

Identity

It soon became clear that instrumentality was not the only reason to participate. After all, many goals are only reached in the long run if at all. Similarly, when it comes to material benefits, costs frequently outweigh benefits. Apparently, there is more in being a movement participant than perceived costs and benefits. Indeed, one of those motives relates to belonging to a valued group (Simon et al., 1998).

Identity is described as a place in society. People occupy many different places. They are student, unemployed, housewife, soccer player, politician, farmer, and so on. The different roles and positions a person occupies form his or her personal identity. At the same time, every place a person occupies is shared with other people. I am not the only professor of social psychology, nor the only Dutch, or the only European. I share these identities with other people – a fact that turns them into collective identities at the same time.

Most of the time collective identities remain latent. Self-categorization theory hypothesizes that an individual may act as a unique person, that is, display his personal identity, *or* as a member of a specific group, that is, display one of the many collective identities he has (Turner, 1999). Obviously, this is often not a matter of free choice. Circumstances may force a collective identity into awareness whether people like it or not, as the Yugoslavian and South African histories have illustrated dramatically and there are other equally or even more dramatic examples throughout human history. But also in less extreme circumstances, collective identities can become significant. Take, for example, the possible effect of an announcement that a waste incinerator is planned next to a neighborhood. Chances are that in no time the collective identity of the people living in that neighborhood will become salient.

Self-categorization theory proposes that people are more prepared to employ a social category in their self-definition, the more they identify with that category. Identification with a group makes people more prepared to act as a member of that group. This assertion refers, of course, to identity strength. Social identity literature tends to neglect that real-world identities vary in strength. But, the strength of group identification may make a real difference especially in political contexts. We may expect that strong identities make it more likely that people act on behalf of their group. The basic hypothesis regarding collective identity and movement participation is fairly straightforward: a strong identification with a group makes participation in collective political action on behalf of that group more likely. The available empirical evidence overwhelmingly supports this assumption.

Movements offer the opportunity to act on behalf of one's group. This is most attractive if people identify strongly with their group. The more farmers identify with other farmers the more appealing it is to take part in farmers' protest. The more women identify with other women the more attractive it is to participate in the women's movement. In addition to the opportunity to act on behalf of the group, collective political action participation offers the opportunity to identify with the movement's cause, the people in the movement, the movement organization, the group one is participating in, or the leader of the movement. Not all these sources of identification are always equally appealing. Movement leaders can be more or less charismatic, or the people in the movement or in someone's group can be more or less attractive. Moreover, movements and movement organizations may be, and in fact often are, controversial. Hence, becoming a participant in a movement organization does not mean taking a respected identity upon oneself, on the contrary. Within the movement's framework, this is, of course, completely different. There the activist does have the status society is denying him. And, of course, for the activist in-group–out-group dynamics may turn the movement organization or group into a far more attractive group than any other group 'out there' that is opposing the movement. Indeed, it is not uncommon for militants to refer to the movement organization as a second family, a substitute for the social life society is no longer offering them. Movement organizations not only supply sources of identification, but they also offer all kinds of opportunities to enjoy and celebrate the collective identity: marches, rituals, songs, meetings, signs, symbols, and common codes.

A complicating matter is the fact that people simultaneously hold multiple identities while movements tend to emphasize a single identity and refer to a single place in society. As a consequence, people may experience that conflicting identities steer behavior in different directions. Individuals might find themselves under cross pressure when two groups they identify with are on opposite sides of a controversy. Indeed, movement activists who challenge their government are often accused of being disloyal to the country. Gonzalez and Brown (2003) coined the term 'dual identity' to point to the concurrent workings of supra- and subordinated identities. They argue that identification with a subordinate entity (e.g., ethnic identity) does not necessarily exclude identification with a supra-ordinate entity (e.g., national identity). In fact, they claim that dual identity is a healthy configuration, as it implies sufficient identification with one's subgroup to experience basic security *and* sufficient identification with the overarching group to preclude divisiveness. There is evidence that indeed people who hold a dual identity are more satisfied with their situation than people who do not (Gonzalez and Brown, 2003). However, if they are dissatisfied, individuals who hold a dual identity were more likely to participate in collective action (Klandermans et al., 2008).

In 2001, Simon and Klandermans published an influential paper on the politicization of collective identity (PCI). In order to become the vehicle of collective action collective identity must politicize, they argued. Shared grievances, common enemies, and a search for third party support are the building stones of PCI, the authors maintain. Some sense of identification with the superordinate political entity seems to be a basic requirement of social and political mobilization, in that it ensures that this entity is acknowledged as one's own social or political habitat. Therefore, politicized identity is by

definition dual identity. More specifically, to the extent that one identifies with the superordinate entity one should feel entitled to make political claims. Similarly, one should feel motivated to get actively involved in the political game, because it becomes one's own game, and one should feel encouraged to approach third parties as potential allies, because they can be viewed as in-group members at the superordinate level, so Simon and Ruhs (2008). Politicization divides people's social environment into allies and opponents and results in polarization. Polarization concerns the process of distancing of the opposing camps. Eventually, this may result in radicalization. Simon (2011) suggests that in a polarized situation, to the extent that PCI is a dual identity including identification with the superordinate polity, PCI has a pacifying effect on politicization and associated collective action in that it prioritizes claims and actions that stay within the limits of normative acceptance in the larger polity. In contrast, collective identities lacking this pacifying effect, such as separatist identities based on more exclusive cultural, ethnic, or religious allegiances, should be more prone to escalation and radicalization. Collective identities must politicize to become the engine of collective action. Typically, politicization of identities begins with the awareness of shared grievances. Next, an external enemy is blamed for the group's predicament, and claims for compensation are leveled against this enemy. Unless appropriate compensation is granted, the power struggle continues. Politicization of identities and the underlying power struggle unfold as a sequence of politicizing events that gradually transform the group's relationship to its social environment, whereby the tactical choices are again shaped by identity. Hence, workers strike and anarchists fight the police.

Ideology

The third motive – wanting to express one's views – refers at the same time to a longstanding theme in the social movement literature, and to a recent development. In classic studies of social movements, the distinction was made between instrumental and expressive movements, or protest. In those days, instrumental movements were seen as movements that aimed at some external goal, for example, the implementation of citizenship rights. While expressive movements had no external goals. Participation was a goal in itself, for example, the expression of anger in response to experienced injustice. Movement scholars felt increasingly uncomfortable with the distinction, as it was thought that most movements had both instrumental and expressive aspects and that the emphasis on the two could change over time. Therefore, the distinction lost its use. Recently, however, the idea that people might participate in movements to express their views has received renewed attention. Attention arising this time from movement scholars, who were unhappy with the overly structural approach of resource mobilization and political process theory. These scholars began to put an emphasis on the creative, cultural, and emotional aspects of social movements, such as music, symbols, rituals, narratives, and moral indignation (Goodwin et al., 2000). People who are angry develop feelings of moral indignation about some state of affairs or some government decision, and wish to make that known. They participate in a social movement not only to enforce political change, but also to gain dignity in their lives through struggle and moral expression.

Social movements play a significant role in the diffusion of ideas and values. Rochon (1998) makes the important distinction between 'critical communities', where new ideas and values are developed, and 'social movements' that are interested in winning social and political acceptance for those ideas and values. "In the hands of movement leaders, the ideas of critical communities become ideological frames" (p. 31), states Rochon, who continues to argue that social movements are not simply extensions of critical communities. After all, not all ideas developed in critical communities are equally suited to motivate collective action. Social movement organizations, then, are carriers of meaning. Through processes such as consensus mobilization or framing, they seek to propagate their definition of the situation to the public at large. A study of flyers produced by the various groups and organizations involved in the protests against the International Monetary Fund and the World Bank in Berlin is an excellent example in this respect (Gerhards and Rucht, 1992). The study shows how links are constructed between the ideological frame of the organizers of the demonstration and those of the participating organizations in order to create a shared definition of the situation. In the social movement literature, such definitions of the situation have been labeled 'collective action frames'.

Social movements do not invent ideas from scratch; they borrow from the history of ideas. They build on an ideological heritage as they relate their claims to broader themes and values in society. In so doing they relate to societal debates that have a history of their own and that history is usually much longer than that of the movement itself. Gamson (1992), for example, refers to the 'themes' and 'counterthemes' that, in his view, exist in every society. One such pair of a theme and countertheme he mentions is 'self-reliance' vs 'mutuality', that is the belief that individuals should take care of themselves vs the belief that society is responsible for its less fortunate members. In my own work, I have demonstrated how in the Netherlands these two beliefs became the icons that galvanized debate and spurred protest over disability payments. While, 'self-reliance' became the theme of those favoring restrictions in disability payment, 'mutuality' was the theme of those who defended the existing system (Klandermans and Goslinga, 1996).

Emotions

Ideology has a significant affective component. Acting on one's ideology is deemed to be one of the fundamental motives of action participation and necessarily charged with emotion. Appraisal and action are socially constructed, that is to say, are formed in interpersonal interaction, especially in the case of politically relevant emotions. Cultural and historical factors play an important role in the interpretation of the state of affairs by which politically relevant emotions are generated. Obviously, appraisal can be manipulated. Activists work hard to create moral outrage and anger, and to provide a target against which these can be vented. They must weave together a moral, cognitive, and emotional package of attitudes. But also, in the ongoing activities of the movements, emotions play an important role. In the literature, two kinds of collective emotions are distinguished – reciprocal emotions and shared emotions – that reinforce each other. Each measure of shared

outrage against an injustice reinforces the reciprocal emotion of fondness for others precisely because they feel the same way. Conversely, mutual affection is a context in which new shared emotions are easily created. Anger and indignation are emotions that are related to a specific appraisal of the situation.

Recent work in sociology and social and political psychology has brought emotions to the study of social movements (Goodwin et al., 2000; van Zomeren et al., 2004). For those of us who have been part of protest events or watched reports on protest events in the news media, this is hardly surprising. Indeed, it is hard to conceive of protest detached from emotions. Emotions can be avoidance or approach oriented. Fear, which makes people refrain from taking action, is an example of an avoidance-oriented emotion. Anger is an approach-oriented emotion and is known to be an antecedent of protest participation (van Zomeren et al., 2004). There appears to be a relation between emotions and efficacy. When people do not feel efficacious, they are more likely to experience fear; feeling efficacious, on the other hand, is associated with experiencing anger. Findings from a study among migrants we conducted confirm this, feelings of efficacy reinforced anger and reduced fear, while in their turn, anger fostered collective action participation while fear undermined it (Klandermans et al., 2008). van Zomeren et al. (2004) show that anger is an important motivator of protest participation of disadvantaged groups. Anger and fear are not the only emotions relevant in the context of movement participation; indeed, other emotions such as hope and despair are proposed as well (Gould, 2009; Stürmer and Simon, 2009). Anger moves people to adopt a more challenging relationship with authorities than subordinate emotions such as shame and despair or fear.

The Transformation of Potential into Action

People who are prepared to take part in collective action do not automatically participate. Potential must be transformed into action (Klandermans and Oegema, 1987). This is what mobilization campaigns are about. Targeting potential participants and turning them into actual participants. Obviously, a campaign will never be 100% successful in that regard. In the course of a campaign, people may loose their sympathy for the movement, or the movement may fail to target or to motivate its sympathizers. As the previous section concentrated on motivating, I will focus now on targeting.

Targeting sympathizers implies answering two strategic questions: Who are the sympathizers? And, How can they be reached? These are two questions every attempt to mobilize must find an answer to. Social networks are of crucial importance in this regard. People are embedded in the social fabric of society (Klandermans et al., 2008). Targeting sympathizers implies knowing where to find them and commanding communication channels that reach them. Movement organizations have two options in that respect: they can try to co-opt existing networks or they can build new networks. Both strategies are mobilization efforts in itself (Boekkooi, 2012). Co-optation is the easier strategy of the two, because it builds on existing commitments to organizations and networks that are the movement organization's allies. There are risks, however. The co-opted organization may use the campaign for its own ends or negotiations with the leadership fail so that it decides to not collaborate. The latter makes it more difficult for the rank and file to cooperate. Yet, co-opting existing networks such as churches, unions, political parties, youth organizations, and the like is frequently applied, if only because it implies an answer to both strategic questions at the same time. On the one hand, it works from the assumption that most members of the allies sympathize with the movement, and on the other hand, it is assumed that these sympathizers can be reached through the allies' communication channels.

Building new networks implies the recruitment of people, who are willing to spend sometimes considerable amounts of time for a prolonged period as a movement activist. It will, therefore, require more effort on the part of the organizer than co-optation of existing networks, but once established the networks are more reliable. The recruitment of such movement activists is a process, which is determined, on the one hand, by factors that influence who is being asked, and on the other hand, by factors that influence who agrees to serve as an activist when asked. As for the first type of factors, a crucial determinant is someone's embeddedness in networks linked to the movement organization, or more specific to the movement organizer, who is undertaking the recruitment effort. Movement organizers tend to recruit first among the people they know and often that suffices. You need activists to maintain the network, and once you have those the return of having additional activist is rapidly diminishing. In fact, long-term activism is one of the forms of activism that must cope with free rider behavior. The people who are asked to serve as an activist understand perfectly well that they are giving most of the sympathizers to the movement a free ride, but that they are prepared to do so because they care. Only people who really care a lot are prepared to sacrifice for the others. They make the effort because they feel that "If [they] do not do it, nobody else will" (Oliver, 1984).

Once the mobilizing structure is in place, the actual mobilization for collective action can proceed (Boekkooi, 2012). Again embeddedness in the social fabric of society plays a crucial role. People may be directly or indirectly connected to the networks of a movement's mobilization potential or not connected at all. Such embeddedness or unembeddedness is of crucial influence on the likelihood of being targeted and if targeted on the likelihood of participation.

Abstract

In this article, we first review classic models of crowd and collective psychology, second outline a contemporary approach to crowd phenomena based on social identity theorizing, and third apply this approach to understand the dynamics of social conflict and social change. We finish by arguing that crowd and collective psychology needs to be moved from the periphery to the center of social psychology and the social sciences and that its continuing exclusion reflects a tendency to under-represent and undervalue resistance to and change of the existing social order.

Introduction

The term 'collective behavior' has many different meanings in different disciplines. It has variously been used to refer to the behavior of the masses in society, to 'publics' or groups organized around a particular issue, to social movements which are organized to effect change around an issue, and to crowds which are physically copresent groups characteristically (but not necessarily) organized around some event (such as a sporting crowd) or some shared concern (such as a protest crowd).

Psychologists, however, have generally concentrated on the last of these meanings. Collective behavior and crowds become largely synonymous. This is the position we shall follow here. Additionally we shall use the term 'collective action' to refer to instances where crowd members act together in a coordinated way.

The psychological study of crowds and collective action attests to a profound conservatism at the core of the discipline. Crowds have tended to be feared and reviled as a threat to the status quo in society. They are an eruption of the primitive, the passionate, and the pathological which has the potential to shatter the order and reason of everyday life.

This leads to two problems: one of commission and one of omission. On the one hand, where crowds and collective action are studied, they are viewed as something exotic and exceptional which reveals the breakdown of ordinary psychological processes and hence has little to tell us about these processes. On the other hand, when it does come to the bread and butter issues that dominate the discipline, crowds and collective action are all but ignored. In psychology we are predominantly concerned with what individuals see, think, and feel and our interventions are designed to change perceptions, cognitions, and emotions. Collective action, it appears, has no place in this at all.

Here, we will examine the traditional psychology of crowds and collective action, how it came into being, and what it has to say about these phenomena. We will then outline a body of recent work which challenges the pathologizing perspective of this traditional work and which shows collective action to be meaningful, purposeful, and both reflecting and also changing the perspectives of participants. Moreover, we will point to the ways in which collective action plays a pivotal role in shaping the perspectives which regulate mundane social life. We will conclude by examining how, despite this, collective action is excluded from mainstream social psychological analysis partly through the way in which change and collective resistance is ignored in the discipline and partly through the way that, even when change is addressed, it is treated more in terms of individual changes among the privileged than in terms of the collective action of the oppressed.

Overall, we shall argue that any social psychology which recognizes the unequal and contested nature of social reality, and which is open to the possibility of social change, must move the study of crowds and collective action from the periphery to the center of the discipline.

Studying Crowds and Collective Action

The Origins of Collective Psychology

There are three layers of influence which shaped the emergence of a systematic collective psychology, predominantly in France, in the late nineteenth century. First, through the centuries, there has been a constant flow of elite invective directed at the crowd. Emblematic is a comment by the Danish philosopher, Soren Kierkegaard: "you must be aware of the opinion of the masses in order to know what to do: the opposite" (cited in Reiwald, 1949: p. 325. Translation by the authors). Second, the industrialization of western Europe through the nineteenth century led to a rapid growth of the masses, concentrated in the cities. This posed an urgent question of social order: would the masses accept their place or would they rise up and overthrow the existing order (Giner, 1976)? Moreover, if the masses in general were a cause of concern, the crowd, as the mass in action, was a particularly rich repository of elite fears (Barrows, 1981). Third, some countries were less stable than others and more vulnerable to mass agitation. Notably, the elites of the French Third Republic were permanently on guard against a wave of oppositional mobilizations: clerical, populist, and, above all, politically radical (Nye, 1975).

Of all the early crowd psychologists, one name stands out, that of Gustave Le Bon. This is less because of his theoretical originality (Le Bon was an expert synthesizer of others' ideas) and more because of his practical and activist bent. Whereas other authors simply noted and bemoaned what they saw to be

the dangerous and destructive tendencies of the crowd, Le Bon's project was to use his understanding in order to harness the power of the crowd for the elite and against the radicals. His book *The Crowd* (1895/1947) reads like a primer on how to manipulate crowds. It was enormously successful, influencing the like of Mussolini, Goebbels, and Hitler, and has been described as the most influential psychology text of all time (Moscovici, 1980).

Classic Crowd Psychology: Debating the Site of Pathology

For Le Bon, crowd psychology is a litany of loss. When people become submerged in a crowd, they lose their individual identity, the source of their standards, and values. Hence they lose their ability to judge and reason. As a consequence, crowds are marked by contagion whereby people simply go along with any passing idea or (because people become incapable of dealing with complex concepts) any passing emotion. These impulses largely derive from an underlying racial unconsciousness which remains once our conscious personalities cease to function. Because this unconsciousness is atavistic and primitive, the behavior of crowds is primitive, sometimes heroic, but above all destructive. Crowd members, having lost their selves and their minds, also lose their morality. People 'descend several rungs on the ladder of civilization' upon entering the crowd, avers Le Bon. Ordinarily reasonable people become senseless beasts. These ideas have filtered into, and continue to influence modern social psychology through the notion of 'deindividuation' (for a critique see Reicher et al., 1995).

However influential Le Bon's ideas may have been outside psychology, in many ways his greatest influence inside the discipline came through those who reacted against them. Notably, Floyd Allport used a large part of his foundational text 'Social Psychology' (first published in 1924) to refute Le Bon's ideas. He denounced the idea of a 'racial unconscious' or indeed any notion of mind separate from the individual as a nonsense. He argued that "there is no psychology of groups which is not essentially and entirely a psychology of individuals" (1924: p. 4). And, most famously, he insisted that "the individual in the crowd behaves just as he would alone only more so" (p. 295).

While the details of Allport's crowd psychology have been largely forgotten, the individualism that he championed has, over time, become orthodoxy throughout social psychology. In crowd research it takes the form of 'convergence' models (cf Turner and Killian, 1972), which propose that the character of crowd action derives from personal characteristics of crowd members. Specifically, violent and antisocial crowds reflect the convergence of violent antisocial or 'riot prone' individuals, the so-called 'riffraff' of society (e.g., US Riot Commission, 1968).

If Le Bon's position can be characterized in terms of the crowd rendering people 'mad,' so Allport's position can be characterized in terms of the crowd as an assembly of the 'bad.' And despite the apparent opposition between the two perspectives, they share a number of fundamental assumptions in common. Both view individual identity or personality as the sole basis for reasoned action. Both see the operation of a reasoning self as lacking in the crowd. Where they differ is whether this lack derives from the crowd process itself (Le Bon) or the nature of the individuals who are attracted to the crowd (Allport). Traditional crowd psychology of whichever variant sees crowds as pathological, the difference lies in whether the site of this pathology lies at the collective or the individual level.

Perhaps the most fundamental criticism of these ideas is that they cannot explain the empirical characteristics of collective action. While both Le Bon and Allport suggest that crowds are characteristically and indiscriminately violent, the historical record tells a very different story. Not only do very few crowd events result in violence but even when they do, behavior is highly patterned. What is more, these patterns are highly meaningful in terms of social belief systems. A case in point is Davis's analysis of the St Bartholomew's Day massacre of 1572 (Davis, 1978). This event, the culmination of French religious wars between Catholics and Protestants, was extremely brutal. Members of each side killed members of the other. Catholics then concentrated on desecrating Protestant bodies, while Protestants concentrated more on desecrating the objects of the holy mass. This, Davis argues reflects the fact that, in the struggle over imposing the 'true' doctrine, Catholics saw heresy as residing in the individual Protestant, whereas Protestants saw heresy as residing more in the rites of Catholicism – the 'demonic mass.' Albeit in the most brutal of manners, each side literally inscribed its beliefs upon the opponent.

The question, then – a question which classic crowd psychology cannot answer – is how can crowd members come together, often spontaneously and in unstructured gatherings, yet still act in coherent and meaningful ways? The obvious answer is that they are governed by social norms, and that is indeed the approach of emergent norm theory (Turner and Killian, 1972). According to ENT, crowd events begin with a period of milling during which prominent individuals (keynoters) determine norms of behavior. But the theory does not explain what does and does not become normative (beyond rooting it in the personal charisma of keynoters and their interpersonal interactions with crowd members). Hence, while ENT can explain the restrained and patterned nature of crowd action, it provides no basis for explaining how the local norms developed in the event connect to larger belief systems and hence it cannot account for the socially meaningful nature of these patterns. It is precisely this issue which led to the development of social identity models which have come to dominate the study of crowds and collective action in recent decades.

Social Identity and Collective Action

The starting point for social identity researchers is a reformulation of the concept of self. Rather than being a singular entity, selfhood is a system that operates at different levels of abstraction. At different times and places, different elements of the system become salient and guide what we think and do (Turner et al., 1987). Specifically, we can either think of ourselves in terms of what makes us, as individuals, distinctive from other individuals ('I' vs 'you' – personal identity) or in terms of what makes the various groups that we belong to different from other groups ('we' vs 'they' – social identity). Moreover, when a given social identity (associated with a specific group membership, such as 'Catholic') is salient, we behave in terms of the beliefs and values that characterize that group.

The concept of social identity has been proposed as an antecedent of participation in collective action (thus we are more likely to participate when we identify with a social group, believe that we have to struggle for the rights of the group; feel angry because we consider that the group suffers from unfair social disadvantage; and also believe that, as a group, we have the power to rectify that disadvantage – see van Zomeren et al., 2012). It has also been studied as a consequence of collective participation (both in terms of the content of identity and the strength of attachment to the group – see Drury and Reicher, 2009). Most of all, however, it has been used to account for the nature of collective action itself, and to contest the pathological perspective of classic crowd psychology.

The starting point for social identity accounts lies in a shift (rather than a loss) of identity when people become crowd members. They begin to perceive themselves in terms of social rather than personal identity. This is at the root of three psychological transformations. First, there is a *cognitive transformation*. Thus, people begin to evaluate their interests and their priorities in relation to group-level beliefs and values (Reicher, 2001). Given the ambiguous and novel circumstances that attend many crowd events, however, this is not a matter of mechanically applying predetermined rules of action. Instead, it is a matter of developing situational norms that translate superordinate categorical beliefs into contextually appropriate behavior. So, there needs to be a process of norm construction, as suggested in Turner and Killian's emergent norm theory. However, critically, only those proposals which are seen as consonant with identity beliefs are liable to become normative and have influence at the collective level. This explains how the patterns of crowd behavior, albeit based on locally elaborated norms, reflect broader belief systems (Reicher, 1984).

Second, there is a *relational transformation*. This derives less from the fact that people start to see themselves as group members and more that they start to see *each other* as fellow group members. They cease to regard those around them as 'other' and more as 'one of us.' This increases the closeness between crowd members: shared identity in the crowd leads to greater trust, respect, cooperation, and mutual support – for a review, see Reicher and Haslam, 2009. Such closeness, combined with a common perspective on the world, allows crowd members to align their efforts, to become more organizationally effective and hence more powerful (Reicher, 2011).

The combination of these two transformations is at the root of a third *emotional transformation*. Many authors, including Le Bon, have focused on the passionate nature of crowds. Durkheim coined the term 'effervescence' to denote the fizzing bubbling excitement of such events. In contrast to Le Bon, though, who considered that heightened emotionality flows from the loss of reason, Durkheim (1912/1995) saw effervescence as flowing from the ability of people to express their ideas in the crowd. This latter approach is very much in-line with social identity accounts. Thus both the development of a common perspective and the development of intimate and empowering social relations between crowd members are in themselves a source of positive emotions. However, in combination, these two factors enable people to enact their collective worldview, to translate beliefs and priorities into lived social practice – even against the opposition of others. It is this, which has been termed 'collective self-objectification' (Drury and Reicher, 2009), which is a crucial source of positive affect (Reicher, 2011).

Far from being mindless and meaningless, crowds are one of the few contexts in which people have both the inclination and the ability to express their social identities in full (Reicher, 2001). Far from being peripheral to everyday social process, crowds provide a privileged site in which to explore the identities that underpin our everyday lives. However, to leave the analysis at that is to miss three crucial things about crowds. First, thus far we have discussed crowds and collective action in terms of a set of people who share a common identity. However, many collective gatherings may involve people who lack shared identity (say shoppers in a high street) or else a number of different groups sharing different identities (say fans of different clubs at a football match). Second, we have examined how collective action is based on the nature of the relevant social identities. However crowds do not just reflect existing social identities and social realities, but they are also a source of change both at individual and social levels (Dixon et al., 2012). Third, our discussion has focused on intragroup processes – the transformations which happen *within* crowds. Yet, as the discussion of collective self-objectification has intimated, crowd events are characteristically intergroup affairs.

As we shall show next, the elaborated social identity model of crowds (ESIM; Drury and Reicher, 2009) seeks to connect these three elements by analyzing how categories are formed and how identities change through the intergroup dynamics of crowd events.

Intergroup Dynamics and Social Change: An ESIM of Crowd Action

As we have seen, different approaches to crowds turn on different conceptions of the nature and dynamics of selfhood – is self-lost in the crowd (Le Bon), accentuated in the crowd (Allport), or else shifted from the personal to the social level? Likewise, the ESIM begins by elaborating the very notion of social identity that underpins social identity analyses of collective action. That is, the construct is defined as a model of our position in a set of social relations along with the actions which are proper and possible in that position. Social identity, then, is a rich representation of social reality. To define oneself as black, for instance, is to see the world in terms of racialized categories, to be subordinated and oppressed, and to be constrained in one's ability to flourish by the acts of powerful white individuals and institutions.

This definition makes the definition of identity into an interactive accomplishment. Our social identity depends not only upon the way we see ourselves but also how we are positioned by others. Most of the time, the way we see ourselves and the way we are seen by others coincide. Hence our interactions consolidate our social position and our sense of self. However, there are times in some crowd contexts where there is an asymmetry between auto- and hetero-perceptions. When that happens we can see dramatic changes in the social identities of crowd members (Drury and Reicher, 2009).

One example of such change occurs in heterogeneous crowds which consist of a plurality of social groups some of whom see themselves as positively aligned with the authorities

in general and the police in particular, others who see themselves as in an antagonistic relationship to the police and authorities. To the extent that the police themselves see the entire crowd as antagonistic and to the extent that they use their power to *act* on this perception (for instance, using coercive tactics to contain or disperse the crowd as a whole), then a series of consequences are set in motion.

First, those in the crowd who previously saw themselves as aligned with the authorities are repositioned as antagonistic and hence begin to redefine themselves, their relationship with the authorities and with fellow crowd members. They begin to see the police as an oppressive out-group acting in illegitimate and oppressive ways. Next, whereas the crowd as a whole was previously segmented into separate groups, their common positioning by the police leads to the emergence of a sense of shared identity and hence the sense of solidarity and empowerment described above. This sense of empowerment enables crowd members to challenge what they see as oppressive crowd action. Finally, the actions of the crowd confirm and consolidate the original police perceptions of the crowd as a homogeneous danger. In this way, a spiral of escalating radicalization in the crowd and of escalating conflict between crowd members and the police is set in motion (for analyses of such dynamics, see Stott and Drury, 2000; Stott et al., 2001).

As can be seen, this dynamic sets in train a whole series of changes. Most obviously, it changes participants' sense of their social position and hence their social identity. As a consequence, it changes the way in which people see their relationship with others – not just the police and authorities. Most immediately, members of the crowd who might previously have been seen as 'other' come to be seen as fellow crowd members. Thus Drury charts how an antiroad building campaign was initially split between locals and seasoned environmentalist campaigners. Locals viewed the environmentalists with suspicion, as unrespectable and as outsiders. However common experiences of harsh policing led to the formation of a single category and to intimate in-group relations between erstwhile opponents (Drury and Reicher, 2009). Such recategorization was not limited to the actual participants in the 'local' campaign. More generally, locals came to see others involved in antiroad campaigns around the country and in conflict with the authorities as in a similar social position to themselves and hence as part of a broad 'oppositional' category. As a result, support and solidarity for their struggles developed. The emergence of more global categories – both within the specific campaign and more generally – went hand in hand with a greater sense of empowerment and hence a greater confidence in taking action (Drury and Reicher, 2009).

Willingness to take action was not just a matter of empowerment. It is also derived from a reconceptualization of what the campaign was all about and hence a change in understanding as to what constituted 'success.' Whereas, to begin with, the locals saw the campaign as a matter of convincing reasonable authorities to protect their community, as they began to see the authorities as unreasonable and antagonistic, so they saw the mere act of resistance and exposing the nature of the State as a crucial achievement in the longer-term campaign. Hence, even if the road was built through the community, the campaign could still be seen as part of a longer-term success in terms of changing government roads policy.

In detailing these various dimensions of change, ESIM does not suggest that crowds always – or even often – result in change. To the contrary, the model specifies stringent conditions which must be satisfied for change to occur: (1) there must be an asymmetry between the self-perceptions of crowd members and the hetero-perceptions of observers; (2) the observer group must have and use their power to impose their perspective on crowd members and hence reposition them in practice. What is more, for the change process to become a self-reinforcing cycle, (3) as a result of observer action and recategorization within the crowd, members must in turn feel empowered to impose their new perspective upon the observer group. ESIM thereby helps to explain both when change does and does not occur. The model addresses the potential for change in and through crowds – a crucial requirement for any adequate psychology of collective action.

Equally, ESIM does not suggest that change, when it does occur, always goes in the same direction and leads to increased antagonism or radicalization. It follows from the model that, where crowd members see police and authorities as an antagonistic out-group but are seen and treated by the police as being respectable and reasonable members of the general community, so there may be shift in identity and action toward inclusion and harmony (Stott et al., 2008).

Finally, ESIM, although specifically developed through the study of crowds, also addresses a whole series of issues which are central to psychology in general: the nature of identity, our perceptions and evaluations of in-groups and others, and our sense of efficacy and its relationship to action. Irrespective of the particular merits or demerits of the model itself it recognizes the crowd as a particularly valuable site in which to study the interactive processes which underpin social understanding and social action.

The Continuing Exclusion of Collective Action

Conformity Bias and the Neglect of Collective Resistance

In recent years, there have been some signs of a growing interest in collective action in social psychology (e.g., van Zomeren and Klandermans, 2011). However, first, the majority of the work concerns the factors that lead people to participate in various forms of protest action and not in the nature or dynamics of what happens when people do actually gather together. Second, for all its growth, collective action remains a niche topic, rarely if ever invoked when more central issues in the discipline (such as intergroup relations, prejudice, and stereotyping) are addressed.

Part of the reason for this can be put down to a strong 'conformity bias' which has marked and continues to mark social psychology (see Moscovici, 1976). This suggests that people generally follow those with status and power. It implies that social understandings are consensual rather than contested. It rules out a study of how people challenge and resist dominant points of view. As we shall see, it is through the neglect of resistance that the importance of collective action is likewise obscured.

Perhaps the most powerful examples of conformity bias can be found in two of the best known studies in all of psychology, Milgram's 'obedience' studies (Milgram, 1974) and Zimbardo's Stanford Prison experiment (Haney et al., 1973). The former is

generally represented as showing that people will obey the orders of an authority figure, no matter how extreme. The Zimbardo experiment is popularly represented as showing that, even without overt orders, people 'naturally' slip into their assigned roles: those assigned to the position of a guard in a simulated prison setting rapidly became brutal. Those assigned to the role of a prisoner became passive and increasingly disturbed.

Yet, in contrast to the received accounts, closer inspection tells a very different picture. Both studies are replete with examples of resistance and of people rejecting orders and roles (see Smith and Haslam, 2012 for detailed critiques of both studies). Obedience varies from 0% to almost 100% in different versions of Milgram's studies, so it is very far from automatic. Equally, in Zimbardo's study, many guards resisted their role, refusing to be brutal and even siding with the prisoners. The prisoners also resisted their allotted position and challenged the guards throughout the study.

What is more, in both studies, the resistance was most likely and most effective when people had collective support. In Milgram's studies, only 10% of participants went up to 450v when they were in the company of two others who dissented. In Zimbardo's study, the dissent was greatest at the start because the prisoners acted in a coordinated manner. This analysis is supported by the results of the BBC Prison Study which demonstrated that the extent to which participants dissented from and were willing to challenge the system was a function of their degree of shared identification with and expected support from fellow group members (Reicher and Haslam, 2006).

Of course, it is arguable that the degree of resistance that was found reflects the artificial nature of such studies and that, in the real world, resistance is rarely found in prisons and other situations of extreme inequality. But in fact dissent and even prisoner control is easily found in even the most extreme carceral (see Haslam and Reicher, 2012 for examples). In the real world, as in psychological studies, such resistance is dependent upon the development of shared identity, mutual support, and effective coordination among the subordinated and oppressed. All in all, the possibility of resistance is always present, however repressive the defense of the status quo. And the emergence of resistance is characteristically bound up with the emergence of collective action. To privilege conformity and stability in everyday life over resistance and change is therefore to obscure the incidence and the significance of collective action in the formation and reformation of groups and intergroup relations.

The Decollectivization of Social Change

It would be wrong, however, to suggest that mainstream social psychology ignores social change. In the period since World War II, the question of prejudice and how to reduce it has been at the very core of social psychology. The dominant approach to the issue of prejudice reduction has been work on the effects of contact between groups. Drawing upon Gordon Allport's foundational text (Allport, 1954), the question has been how and under what conditions contact (notably between black and white people) leads to more positive attitudes. By now there is an overwhelming amount of evidence that contact will generally lead to greater liking between dominant and subordinate group members (Pettigrew and Tropp, 2006). Such findings have led researchers to conclude that contact is the royal road to change our unequal society. But there is a problem with this work. It does not lie so much in the well-documented link between contact and liking, but in the assumption of a link between liking and social change. Indeed there are a variety of reasons for thinking that liking may not improve relations of social inequality (Dixon et al., 2012).

There is ample evidence that dominant group members can like their subordinates without believing that they should be equals or indeed supporting moves toward equality (Dixon et al., 2012). This is most obvious in the case of gender relations: men can like women while treating them as inferiors – something that is encapsulated in the notion of 'benevolent sexism' (Glick and Fiske, 2001). However, even in more extreme cases, like that of slavery, there is evidence that many owners looked kindly on their slaves and felt that ownership protected inferior creatures from the depredations of the free-market. Thus, they could depict slavery as "a blessing to both master and slave" (Fox-Genovese and Genovese, 2005: p. 515). However such fondness lasted only as long as slaves accepted their place. Should they challenge it, benevolence would rapidly change to anger and brutality. But despite that, there were multiple challenges and indeed slave revolts were critical to the eventual abolition of slavery itself.

The same is true for most entrenched forms of inequality. The end of apartheid, the introduction of civil rights to African-Americans, and the granting of votes to women, all were a result of collective action. To cite Barack Obama's speech in Selma on 4 March 2007 "I'm here because someone marched." It is hard to think of circumstances where equality has been freely granted through the individual kindness of the dominant group members. On the whole it has been claimed through the collective mobilization of subordinate group members. That is why it is particularly worrying that contact may have a demobilizing effect on them. Thus there is growing evidence that increasing contact and increasing the extent to which subordinate group members like dominant group members may actually decrease the extent to which the former will demand and agitate for change in part at least because it reduces their perception of racial discrimination and increases their perceptions of social mobility (Wright and Lubensky, 2009).

So, even where social psychology does address issues of social change, collective action tends to be neglected. This is not just a conceptual issue. The focus on psychological rather than sociostructural outcomes leads to the employment of strategies that demobilize people and therefore leave structural inequalities in society intact.

Conclusion

In this article we have considered both how crowds and collective action have been studied in social psychology and also how they have been neglected. We have encountered evidence to show both that the study of collective action allows us to understand the nature of social action and social change, and also that collective action is critical to achieving social change. Our conclusion is that a social psychology which

marginalizes collective action will be both intellectually deficient and socially conservative. For both reasons, we reiterate that the study of collective action needs to be moved from the periphery to the core of the discipline.

This article is a revision of the previous edition article by J.L. Wood, volume 4, pp. 2204–2208, © 2001, Elsevier Ltd.

Abstract

The article begins with a selective summary of contributions to the study of collective behavior by four historical figures: Charles Mackay, Gustave Le Bon, Alexis de Tocqueville, and Karl Marx. They are considered both as figures on their own and, taken together, as expressing dilemmas that have characterized the field throughout its history. These dilemmas are scope of the subject matter of collective behavior, psychological versus social explanations, the role of 'irrational' forces, and analytic versus evaluative assessments of collective behavior. The remainder of the article reviews the past half-century, both on its own and as expressing the ongoing dilemmas. The 'approaches' summarized are 'collective dynamics,' emergent norms, Smelser's general theory, resource mobilization theory, contentious politics, opportunity structure, framing and frame alignment, and the role of emotions in explanation. The article closes with a few summary observations on diverse tendencies that have characterized the development of the sociology of collective behavior.

Four Classical Approaches

It is instructive to consider a number of historical figures who made the field of collective behavior a preoccupation. These are Charles Mackay, Gustav Le Bon, Alexis de Tocqueville, and Karl Marx. To my knowledge, these figures have not been grouped together before. I do so because of their importance for the genesis of the field and because, together, their works lay down surviving emphases and generate several dilemmas in scholars' descriptions and explanations of collective behavior.

Charles Mackay (1812–89)

One of the most dramatic if not sensational treatments of collective phenomena is found in a book by this nineteenth-century Scottish poet, songwriter, author, and anthologist. He called it *Extraordinary Popular Delusions and the Madness of Crowds* (2012 [1841]), a title that reveals much about the book's tone. He identified his focus as nations' and individuals' "whims," "peculiarities," and "excitement and recklessness" (2012 [1841], Preface). The book consists of colorful historical descriptions of an incredible array of phenomena including financial crazes, alchemy, prophecies, the Crusades, witchcraft, dread of haunted houses, speech fads, popular adoration of thieves, dueling, and ordeals. Reading the book 170 years later, one remains glued to its stories, its wit, and its ironical observations.

We should not hold Mackay to standards of scientific explanation and evidence that were not available to him. His time was mainly prescientific, except for nineteenth-century economics and psychology. Yet if we examine his accounts from the standpoint of scientific desiderata, they are wanting in several respects, which will now be described.

Delineation of Subject Matter

Mackay appeared to include anything he found in the historical record that kindled his interest, with the result that his methodology is that of a historical vacuum sweeper. The boundaries and subdivisions of his subject matter – called for in scientific explanations – are absent, except for their apparently common characteristics of folly and madness.

Interest in Variation

Because Mackay regarded the tendency to madness to be basic to human nature, the fundamental reason for their occurrence of follies appears to be that they express this. This yields an unsatisfactory scientific handle, because all science rests on the explanation of variation in phenomena. To treat them as recurrent expressions of a universal human propensity cannot discriminate between their occurrence and nonoccurrence or other variations.

Although this diagnosis is generally correct, a few observations in the volume suggest not only variations but also crude explanatory mechanisms. Mackay observed, for example, that "Men … go mad in herds, while they only recover their senses slowly, and one by one" (Preface), presaging Le Bon's later emphasis on the independent power of the group. Another instance: "Credulity is always greatest in times of calamity" (p. 144). This is a version of deprivation theory (cryptic, to be certain), at least noticing the problem of why collective delusions cluster more in some circumstances than others. As a general rule however, Mackay's descriptions are devoid of what we would now call causal forces or mechanisms.

Scientific Neutrality

Mackay's work reveals no discernible line between his descriptions of his chosen phenomena and his moral stance toward them. As such they are simultaneously both objective and silly, delusional, misguided, and often dangerous. In the generations since Mackay we have come to objectify such phenomena and insulate them from praise or blame, but as will become evident later, the field of collective behavior has had an impossible time of escaping moral and political preferences as well as conflicts about its subject matter, particularly its apparent irrationality and emotionality.

Gustave Le Bon (1841–1931)

In 1895 a small book, called *The Crowd* (2001 [1895]), was written by this French social psychologist, sociologist, and amateur physicist. It is probably the most influential work in the history of the study of collective behavior. Part of its impact lay in how he framed his study; not only did he advertise his work on crowds as established psychological knowledge, but he also used the most extreme psychological language to describe them. Moreover, he related his work to the sweep of history, proclaiming contemporary times to be an "era of crowds" (p. x). He attributed this era to the rise of democracy and the demise of stabilizing religious and political traditions (dramatized by the French Revolution). This alone assured that the book would be the source of continuing controversy.

Le Bon dwelt on the characteristics of the crowd mind: mentally inferior, incapable of reason, impulsive, fickle, suggestible, credulous, incapable of compromise, subject to illusions, intolerant, dictatorial, and amoral (but capable of both moral degradation and lofty morality). Above all this mentality was unconscious, reflecting in Le Bon's work the late nineteenth- and early twentieth-century preoccupation with unconscious forces. All these characteristics are not to be found in individuals; they are a product of the crowd as such (Le Bon's version of the 'group mind'), and the immediate causes are found in the mechanisms of a sense of omnipotence, contagion, and suggestion. Reflecting a bias of Victorian times, Le Bon singled out primitives, Latin races, women, and children as especially susceptible to crowd-like thinking.

Among the 'remote' (i.e., historical) factors that gave rise to the era of crowds were a people's racial characteristics, the destruction of traditions, and the decay of regulating political and social institutions, all of which check the formation and activity of crowds. Consistent with this diagnosis, he singled out juries, election campaigns, and parliamentary assemblies – all associated with democracies – as outright 'crowds,' demonstrating the same excesses.

For half a century *The Crowd* and its adaptations dominated psychoanalytic group psychology (Freud, 1955 [1921]), social psychology (e.g., Trotter, 1916), and sociology (echoing into Park and Burgess, 1924; Blumer, 1951). Since World War II its influence has continued in sociology, though mainly in a negative sense, in that developments external and internal to the field shifted its emphasis in more rational directions, with Le Bon as its principal casualty.

From a methodological point of view, Le Bon's treatment of crowds also suffers from indistinct and sprawling conceptual boundaries and a looseness of causal explanations, though he did organize multiple causes into remote and immediate, and social and psychological. Unlike Mackay, moreover, he proclaimed his method to be scientific, that is, not influenced by "opinions, theories and doctrine," even though his topics generated 'impassioned controversy.' Though he betrayed this outlook by flooding his work with gross moral and political judgments, it is notable that he also appealed to the logic of science and dispassion as legitimizing criteria.

Alexis de Tocqueville (1805–59)

More than 20 years after his immortal *Democracy in America*, Tocqueville developed an account of the French Revolution, under the title, *The Old Regime and the French Revolution* (1945 [1856]). In his analysis he also distinguished between remote and more recent causes. Among the former he specified (1) the tendency for governments to centralize; which led to (2) the partial deterioration of feudal institutions – retention of privileges but loss of authority; (3) at the same time, certain classes, notably the bourgeoisie and the peasants, had gained in wealth, but were excluded from other advances within the social order; this produced widespread feelings of relative deprivation in those classes; this produced (4) an isolation and conflict among groups; which was aggravated by (5) a general tendency of group members to imitate one another; out of these forces grew (6) a general ideology calling for wholesale social change, based on equality and simplicity; this kind of thinking was also an expression (7) of a 'French temperament' that favored total diagnoses of society and comprehensive programs of change. As more proximate causes, Tocqueville mentioned repressive activities and hasty, ill-conceived reforms by the government that affected timing and direction in the actual revolutionary overthrow.

Though ad hoc in appeal to causes, Tocqueville's study reveals several special features. He relied on an abiding distinction between longer term predisposing causes and immediate precipitants. He developed a multicausal analysis that included social–structural (e.g., government, relations among classes), psychological (e.g., relative deprivation), even political (state aggrandizement) and cultural ('French temperament') forces. Finally, though Tocqueville is generally heralded as a 'liberal' in political preference, his analysis of the French revolution is remarkably dispassionate, free of intemperate value judgments and emotional reactions. His summary of the accumulation of causes was that the revolution was "a foregone conclusion."

Karl Marx (1818–83)

As with Tocqueville, we note a specific social movement central to Marx's economic and social theory – the rise of a worker revolution that will destroy capitalism as a system and usher in a propertyless and stateless society, the communist system.

Marx's ultimate explanation of the proletarian revolution traces to fundamental economic principles, specifically the labor theory of value and its derivatives. The highly elaborated theory's essence is that the amount of labor imparted to a commodity determines its value. In the organization of capitalist production, it becomes possible, even necessary for capitalists to enter this process and expropriate a portion of this value, in the form of what Marx calls "surplus value" by using strategies such as lengthening the working day and using female and child labor, but above all by gaining technological advantage in the competitive capitalist system. This extraction is translated directly into profits, and more importantly, the extraction of surplus value is the principal instrument and determinant of labor exploitation. This ever-increasing exploitation is the engine for worker reaction and ultimately for their destruction of the capitalist system through violent revolution.

In one sense Marx's theory of revolution is mechanical, reflecting the immutable forces of capitalist production. However, he developed a kind of 'learning theory' whereby workers progress from a condition of false consciousness of

their class position to a truly revolutionary consciousness. In the early stages, workers are isolated, in competition with one another, and disorganized; they are capable of only isolated forays against the means of production (for example, machine breaking) and misguided attacks against the remnants of the feudal ruling classes. As workers gather into greater proximity with one another, and as the advance of industry obliterates their differences, they become more mobilizable into collective action groups such as trade unions, and are able to compel their recognition and attain legislative victories such as limitations on hours. Finally, as the contradictions of the capitalist system worsen, a revolutionary party is formed, consisting of the proletariat and that part of the bourgeoisie that has been driven into the ranks of the workers. That party ultimately overthrows the capitalist system.

I include Marx – seldom considered a scholar of collective behavior – among the illustrative historical scholars for two reasons. First, his explanation of revolution is deterministic in the extreme, relying on the unfolding of the economic laws of capitalist society. Human agency plays a role in mobilizing for and executing the revolution, but that agency is more profoundly determined by structural forces. Second, the emphasis is overwhelmingly macroscopic, ignoring any special 'mentality' of participants in the worker movement beyond its progress toward increasing class consciousness.

Enduring Dilemmas Posed by These Historical Accounts

Assuming it is a legitimate exercise to compare and contrast these historical figures, it is also appropriate to analyze several dilemmas that their work – considered together – poses for the study of collective behavior. These dilemmas, moreover, extend to the present and impart understanding to the directions, strengths, limitations, and ambiguities of this subfield of sociology:

Dilemma 1

What subject matter is covered by the term, 'collective behavior'? Specifically, does it refer to episodic collective outbursts or does it include social movements? Most treatments have avoided this classificatory dilemma by creating open-ended categorical lists including panic, craze, stampede, crowd ecstasy, mass hysteria, mass delusion, riot, lynching, fad, fashion, spread of collective mood, social protest, reform movement, revolutionary movement, religious cult, and religious revival. Some have argued that there is a continuity among collective behavior and social movements and have grouped them together; others find that the two classes of social behavior are separate beasts, to be explained separately. The general confusion over proper terrain has also produced diverse generic terms – mass phenomena, mass movements, mass behavior, collective action, and collective dynamics, as well as lesser candidates such as collective moods and opinion drifts – none of which have 'stuck.'

There is no clear resolution of this dilemma, because inclusion and exclusion vary according to the defining characteristics assigned to the diverse phenomena. Empirical reality alone does not dictate a solution; the mode of conceptualization also plays a role. If spatial contiguity and face-to-face interaction are evoked as defining characteristics, for example, generic differences between episodic outbursts and social movements are evident; if common emotions or belief systems are the defining characteristics, then more similarities may be found. In this article I include reference to social movements as well as collective outbursts for two reasons: first, in the history of investigations they have sometimes been lumped together; and second, despite the development of separate strands of research in recent decades, the two classes of phenomena raise common issues of internal dynamics, explanation, and consequences.

Dilemma 2

The two most common explanatory frameworks for collective-behavior phenomena are the psychological and the social (although cultural factors have appeared and political explanations have surged in recent decades). In principle the distinction between the psychological and the social is straightforward: psychological refers to internal orientations of actors, perhaps intensified in groups through processes of social interaction but still psychological in essence; sociological explanations rely on social–structural dimensions, including cleavages, dislocations, and malintegrations in the larger society. In practice, however, these two types of explanation have been so fused in emphasis that is impossible to separate them neatly and without distortion.

In this article I bow to the realities of history, which has refused to honor any neat or consistent separation of psychological and sociological approaches to collective behavior, however defined and explained. Different research traditions stress one aspect or the other, of course, and these stresses have different implications, as we will demonstrate. But to honor the complexity of this field, it is obligatory to include both levels of classification and explanation, as well as others.

Dilemma 3

Insofar as causes are psychological, are the driving forces conceived as irrational (real, based on distortion, blind, misdirected) or rational (reasonable, calculated, deliberative, intelligible, or right because they reflect the laws of history)?

Dilemma 4

The phenomena identified as included in collective behavior themselves generate – perhaps universally – strong emotional and evaluative reactions among those who participate in such behavior, those who witness it, and those who study it. As a result, social observers, including social scientists, forever allow evaluative reactions – open or subtle – to become a part of their assessments. These reactions are emotional, moral, and political, or some mix of these. The history of the field, in consequence, has been one of bias imparting, bias exposing, bias denying, denying of bias denials, and rebiasing, despite contravening scientific dictates to be objective and dispassionate. Other sociological specializations – family, class, religion – reveal the same tendencies, but collective

behavior seems a strong competitor for first place in this questionable race.

Historical Threads during the Past Half-Century

For reasons not evident, the years surrounding 1960 produced several general, ambitious treatments of collective behavior. (At the beginning of that decade, Lang and Lang (1961, p. vi) declared that up to that time the field of collective behavior had "somewhat fallen into disrepute" and "had not kept pace with developments in other fields.") Taken together, these works simultaneously constitute shifts in emphasis, innovation, and consolidation. The first was a general work on social processes, by Turner and Killian (1957). Accepting the premise of the Chicago school (especially Blumer, 1951) that collective behavior arises from a breakdown of social control and integration, and itself is an unstructured, noninstitutionalized expression, they developed a more positive theme whose influence has persisted: collective behavior is a *process* in that in its course of development it develops emergent and increasingly explicit norms that shape the goals, strategies, tactics, and envisioned outcomes of any given episode or movement. In this way Turner and Killian, while retaining residues of the 'irrationalist' elements that survived in the Chicago school, added a more purposive, positive, and creative element. A second major book by Lang and Lang (1961), a synthetic work, emanated from the Chicago school as well. It was mainly social–psychological in emphasis, though acknowledging social–structural background influences; it also was influenced by the mass-society and mass-behavior perspectives, salient at the time. Their book was widely recognized as a valuable comprehensive statement, but was not received as innovative, and has not persisted in influence. However, it was sufficiently visible at the time that it earned them the authorship of the entry on collective behavior in the *International Encyclopedia of the Social Sciences* later in the decade (Lang and Lang, 1968).

The third work, by Smelser (1962), involved a self-conscious shift from the social–psychological tradition of collective behavior to a more explicit social–structural or sociological direction. He defined collective behavior as "mobilization on the basis of a belief that redefines social action," and made an effort to integrate collective outbursts such as panics, crazes, and hostile outbursts as well as reform and revolutionary movements under this definition. He developed a comprehensive "value-added" explanatory framework that conceived episodes of collective behavior as multiply determined by a narrowing series of conditions (causes): structural conduciveness, or the possibility (opportunity) for such episodes; structural strain (which encompassed a range of deprivations, malintegrations, and ongoing social cleavages); growth and spread of a generalized belief; precipitating factors; mobilization of participants for action; and responses to collective actions by agencies of social control. His emphases on conduciveness, mobilization, and agencies of social control survived into subsequent, more politically oriented approaches. Smelser himself eschewed psychological definitions of collective behavior, and in particular, implications that "persons involved … are irrational, that they lose their critical faculties, that they experience psychological regression, that they revert to some animal state" (Smelser, 1962, p. 11). However, in his exposition of generalized beliefs, he identified a tendency for these to "short-circuit" from generalized hopes and aspirations into specific promises and solutions (suggesting, perhaps, a magical element), and, used the colorful but unhappy phrase "action of the impatient" to describe episodes of collective behavior. Many critical reactions to his work, developed in the years after the book's appearance, seized on these descriptions and consigned Smelser's work to the irrationalist (and implicitly politically conservative) tradition.

In the late 1960s the study of collective behavior took a decisive turn. The origins of this emanated from the larger society, as movement after movement cascaded through the nation – civil liberties, violent urban protests, student activism, antiwar agitation, affirmative action, new activity in one minority group after another, women's liberation, and gay rights. It was a decade-and-a-half of ferment sandwiched between the quiescent Eisenhower years and the conservative Reagan years. Most of the movements came from leftish territory and spoke on behalf of the disprivileged. Accordingly, they excited the sympathy and support of many social scientists, already leftish in their political leanings. Sociology, long attuned to social problems and social inequalities, was perhaps most affected.

In the study of collective episodes and social movements, the 'turn' was a complex psychological and political one. In general attention turned *away* from the psychological characteristics of participants, but in particular it evolved toward a psychology that involved purposive and reasonable if not rational pursuit of legitimate goals. This augmented representation of rationality informed the turn of the 1970s, and in a few cases (Olson, 1965; Oberschall, 1973), stronger assumptions deriving from models of economic rationality were adopted. The turn was political in four senses:

- Political variables began to take over (the brief definitional flurry over whether the Watts disturbances were 'riots' or 'protests,' and the continuing ambivalence toward the term 'riots' remains). (1) Movements were treated as purposive efforts to mobilize resources such as financial support, member commitment, the media, personal networks, and supportive groups (McCarthy and Zald, 1977). One consequence was a shift away from a focus on causes of social movements toward a focus on reasons for their success or failure. (2) The 'opportunity structure' for movements – meaning mainly political opportunities and constraints (e.g., Tarrow, 1983) – gained salience. (3) The political emphasis reached a kind of apex with the treatment of collective phenomena as 'contentious politics' (McAdam et al. (2001). This last effort appeared, in effect, to treat much of what had been considered collective behavior as part of the political process. In these reorientations the emphases on participant motivation, social psychology, ideology, culture, and affective dimensions as characteristics and/or determinants gravitated toward the invisible (Chazel, 2001).
- Scholars and teachers in the field became politically friendlier toward uninstitutionalized protest, even though

this shift in affect was often muted or disguised in the face of continuing force of the importance of scientific dispassion in social science inquiry.

- In the profession and in university and college curricula the study of collective behavior and social movements assumed greater salience, manifested in particular by the formation of a separate section on Collective Behavior and Social Movements in the American Sociological Association.
- The 1960s–1970s involved a wholesale assault on almost all past traditions of collective behavior, which were regarded as 'irrationalist' psychologically, misguided conceptually, and implying a sympathy or identification with the ruling classes, the status quo, the 'establishment,' and authorities. Some of this might be written off as the general tendency of social science innovators to declare the past mistaken and irrelevant, but in this case a major paradigmatic reorientation was accomplished. These multisided political emphases produced the greatest surge of literature in the history of the field – a flood of conceptualization, theory, case studies, comparative research, readers, handbooks, and texts on social movements in the last several decades of the twentieth century. The interpretation of large-scale historical revolutions, highlighted by the work of Skopcol and the continuing influence of Tilly, emerged into a subfield of its own. The study of short-term episodes such as panic, scapegoating, and crazes revealed little innovation, but the occurrence of and preoccupation with disasters (such as 9/11 and Hurricane Katrina, produced bursts of empirical studies and commentaries (Dynes and Tierney, 1994; Brunsma et al., 2010).

As the dominant political themes of the 1970s either became established research traditions or subsided in the face of criticisms, new emphases appeared. Many of these changes, it can be argued, constituted a 'cultural turn,' reflecting wider trends toward multiculturalism, diversity, and more vaguely, postmodernism in the larger society and in many humanities and social science fields. In sociology in particular, this impulse found expression in a heightened preoccupation with 'identity movements,' in which personal cultural self-consciousness and personal dignity are conspicuous (see Reger et al., 2008). These movements mainly include those based on the assertion of racial, ethnic, gender, and sexual preference identities. Emphasis on them paralleled a surge of interest in 'identity politics' in political science and the concept of 'self-identity' in social psychology (see Tajfel, 1982).

In Western Europe a related cultural thread emerged. It went under the name of 'new social movements' (Melucci, 1980; Touraine, 1981). Of course, the adoption of the term 'new' implied an 'old.' In this case the old were the labor and socialist movements, bred by and ranged against capitalist exploitation; these were assumed to have lost their energy and resonance as societies evolved into postindustrial forms. The new were seen as reflecting continuing and new contradictions of postindustrialism, including inequality, domination, and repression. However, they did not stress income and economic security, but rather 'life-world' concerns of personal identity, personal life, neighborhood, environment, gender, and peace, and antiwar themes (Kriesi et al., 1995). Scholars' enthusiasm for these two cultural approaches appears to have subsided from a torrent to a more routine preoccupation.

A third development in late twentieth century, also in many ways 'cultural,' goes under the name of 'framing.' Invented decades ago, and tracing ultimately, perhaps to W.I. Thomas' definition of the situation, the concept was vitalized in the 1980s in relation to social movements (Snow and Benford, 1988). Basically, the concept refers to ideas that diagnose issues, envision solutions, motivate participants, provide identity, define agency, generate strategies, and specify grievances for social movements. The concept has become highly elaborated into a subfield and widely applied, and criteria for effective and ineffective framing have evolved. Proponents of the perspective acknowledge its kinship to 'ideology' (Snow and Benford, 1996) and its link to 'culture' (Zald, 1996), but also insist on its uniqueness and advantage. The concept may also be regarded as a return of themes thought to be neglected in the politically oriented approaches of the 1970s.

Though not expressive of a cultural turn, a new, or rather revived interest in the role of emotions in social movements has also appeared, in part critical of the perceived over rationality of recently dominant approaches, in part reflective of the general revitalization of affective dimensions in psychology in recent decades, and in part a reflection of a more general trend reflecting, for example, 'emotions in economics' and 'emotions in organizations.' While remaining generally inchoate, the 'emotions' perspective has revitalized reflexive emotions, affective bonds, moods, and moral reactions as relevant dimensions (Goodwin et al., 2004).

Finally, notice might be taken of a recent instance of the general tendency of the field of collective behavior to take an interest in and give emphasis to particular novelties as they appear in the real world. I refer in this case to the emergence of both interest and enthusiasm about the Internet as an instrument of collective mobilization – especially under repressive regimes that have difficulty in controlling it. The burst of interest is especially evident in the Arab Spring and other Middle-Eastern uprisings. More generally, electronic communication may well be a major redefining force for social movements and politics in general.

Concluding Remarks

The sociology of collective behavior, over its history, has revealed a number of diverse and not altogether consistent tendencies: (1) a stubborn persistence, and in some periods, impressive growth and accumulation of knowledge; (2) a certain dialectic, with competing perspectives, explanations, and theories waxing and waning but none disappearing altogether; (3) unusually high levels of paradigmatic conflict; (4) a struggle between scientific and evaluative impulses; (5) a tendency to 'chase' emerging phenomena in the larger society; and (6) an assured future, given the centrality of its subject matter in the continuing processes of democratization and globalization, both of which nurture uninstitutionalized political protest in the political process.

Collective Beliefs, Sociological Explanation of

Michel Dubois, French National Research Center, CNRS, Paris, France

Abstract

The explanation of collective beliefs is a central question for sociologists and generally for all social scientists. If the 'market' of ideas and beliefs is frequently described in terms of individualization, this should not be overinterpreted by asserting that the realm of collective beliefs is over. The dissemination of individual beliefs frequently converges in collective trends that can be sociologically identified and analyzed. We propose to distinguish five main modes of sociological explanation of collective beliefs – positional, interactional, emotional, cultural, and rational – and analyze their conditions of scientific robustness.

The explanation of collective beliefs is a central question for sociologists and generally for all social scientists. Alexis de Tocqueville, Karl Marx, Max Weber, Gabriel Tarde, Emile Durkheim, Vilfredo Pareto, Max Scheler, and Karl Mannheim, to name a few founding fathers of the sociological tradition, all have devoted a lot of time and energy to this question. Beyond their differences of methods and concepts, they share the general idea formulated by Durkheim in his *Elementary forms of religious life* (1912/1995): the explanation of collective beliefs constitutes the center of gravity of the overall sociological discipline. Although of decisive importance for past and contemporary sociologists, this project remains confronted by certain difficulties, some more challenging than others. At first we will review three of the most commonly discussed difficulties. Next, a detour to classical and contemporary sociological studies will demonstrate the diversity of the sociological modes of explanation of collective beliefs. We will focus on five main factors or social mechanisms. Finally we will identify some of the general criteria used by sociologists to evaluate the respective merits of these explanations. We will be interested in the reasons why many contemporary sociologists consider the generalization of the principle of 'symmetry' as representing significant progress in the sociological explanation of collective beliefs.

Why Is It Difficult to Explain Collective Beliefs?

A first difficulty related to the sociological explanation of collective belief is the existence of collective belief itself. At the beginning of the twenty-first century, are there any collective beliefs left to explain by sociologists? It is a well-known fact that the landscape of collective beliefs has dramatically changed since the period of the founding fathers of sociology. The market of ideas and beliefs is nowadays described in terms of balkanization and individualization (Boudon, 1999; Hervieu-Léger, 2010; Bronner, 2011). Whereas past collective beliefs, religious or political, were massive in terms of scale, cohesion, and diffusion, contemporary collective beliefs are subject to a double process of deinstitutionalization and subjectivization. The modern propensity to 'cognitive tinkering' regularly described by sociologists weakens the long-established relation between believing and belonging. Individuals tend more and more to 'believe without belonging' (Davie, 1994), hence a greater variety of social beliefs. This of course should not be overinterpreted by asserting that the realm of collective beliefs is over. The dissemination of individual beliefs frequently converges in collective trends that can be sociologically identified and analyzed. Collective beliefs still exist, but their form and capacity to circulate have obviously changed. New information technologies, such as the Internet, modify the way individuals produce and diffuse their ideas.

A second difficulty regularly associated with sociological explanation of collective beliefs is their extreme diversity. What is the common thread in beliefs related to the competence differences between male and female (Ridgeway and Correll, 2004; Rashotte and Webster, 2005), God's influence in everyday life (Schieman, 2010), origins of poverty (Lee et al., 1990; Hunt, 1996) and social or racial inequality (Kluegel and Smith, 1981; Kluegel, 1990; Krahn and Harrison, 1992; Evans, 1997; Schuman and Krysan, 1999; Bailey, 2002; Galland et al., 2013), life after death (Greeley and Hout, 1999), the existence of Santa Claus (Bronner, 2004) and paranormal phenomena (Boy and Michelat, 1986; Markovsky and Thye, 2001; Renard, 2010), the origins and prevalence of AIDS (Natras, 2013), and personal sensitivity to medications (Horne et al., 2004)? Sociologists have different methods to characterize the state of minds and representations about all kinds of topics, but in what sense can we consider that they all are studying various aspects of the same general object – collective beliefs?

One way to answer this question is to go beyond appearances and consider what is common to all of these peculiar objects. Whatever the topic, the term 'belief' implies the act of believing a proposition x as true and thus the conscious feeling of confidence about the reality of x. Believing constitutes a type of action and a form of intentionality. But are all beliefs really equal in terms of action and intentionality? Do we believe in the same way in the competence differences between male and female as we do about the existence or non-existence of life after death? Sociologists generally distinguish beliefs that are consciously endorsed with a strong level of individual or collective reflexivity from others that are more or less taken for granted with a low level of individual or collective reflexivity. Hence the tendency to disassemble the general category of 'collective belief' into multiple subcategories to account for the diversity of the modes of production and acceptance of opinions and representations (Clément, 2010).

This leads us to a third difficulty: confronted by the internal complexity of the category of collective belief, sociologists have sometimes multiplied the explanatory categories, and in so doing have forgotten that the vocation of any explanatory theory is to establish the simplicity behind the apparent complexity. In a well-known article intended to provide a general theoretical framework for the sociology of knowledge, Merton (1945) summarizes the nature of the sociological explanation in the following way: to establish the correlations between collective beliefs, conceived as dependent variables, and "the other existential factors of society and culture" conceived as independent variables. If such a formula makes it possible to unify many sociological studies devoted to the explanation of collective beliefs, this unity remains, however, purely 'formal.' In practice, an overview of the sociological literature shows that there is no real consensus among sociologists on the nature of the social mechanisms at work in the production and dissemination of beliefs. Collective beliefs are shared representations by individuals or groups. But what do individuals or groups have in common that generates the collective nature of their beliefs? What are the 'existential factors,' to use Mertonian terminology, that explain at least partly the ability of certain beliefs to be produced, diffused, and shared by multiple individuals? Without trying to be exhaustive, we may analytically distinguish between five main factors or social mechanisms, albeit slightly overlapping, generally related to the production and diffusion of collective beliefs.

Collective Beliefs and Social Mechanisms

Historically, one of the first factors discussed by sociologists is social position or social status. Why do individuals share the same beliefs? Because they share the same social position or the same socioeconomic status. Marx's main contribution to the sociology of ideology is the general thesis that individuals having a similar position in the social order (dominant or dominated) also have similar social interests and by extension a similar set of impressions, illusions, ways of thinking, and some philosophical conceptions. There is no need to return to the traditional theory of ideology; contemporary research has repeatedly documented a consistent relationship between social position and representations about poverty or socioeconomic inequality (Nilson, 1981; Kluegel and Smith, 1986; Lee et al., 1990; Hadler, 2005). For example, two types of representation on the origins of poverty are generally opposed: individualist accounts and structuralist accounts. The former posits that social inequality is due to disavantadged individuals themselves and is associated with inaction regarding that inequality. The structuralist category holds that there are external factors systematically disfavoring the disadvantaged individual. According to numerous studies, notably in the United States, being white, older, male, and of higher income increases the propensity to favor individualistic over structural beliefs. Inversely, black Americans, who often occupy lower social positions, are more critical about the social order and tend to favor structural beliefs over individualistic beliefs. This relationship between belief and social position is of course not limited to socioeconomic representations. In their study on the diffusion of parascientific beliefs, Boy and Michelat (1986) distinguish two sets of beliefs: astrology and paranormal phenomena. These two sets are not equally distributed among the various socioeconomic status groups. High socioeconomic groups tend to favor paranormal beliefs whereas middle or low socioeconomic groups are more inclined toward astrology. This inequal socioeconomic distribution is also observed by Schieman (2010) in his study on beliefs about God's influence in everyday life: "Compared with high socioeconomic status (SES) groups, low SES individuals tend to profess higher levels of divine involvement and control even when both groups share similarly low levels of religious involvement. These patterns concur with the claim that low SES groups tend to hold more orthodox beliefs than high SES individuals-regardless of their actual participation in religious activities" (p. 44). All of the collective representations – socioeconomic beliefs, parascientific beliefs, religious beliefs, etc. – are discussed in terms of positional effect. However, if a simple psychology of interest gives real support to the positional explanation of socioeconomic beliefs (each position is supposed to determine a sense of self-interest for each individual), the relation between social position and parascientific or religious beliefs remains more enigmatic. Sociologists generally try to overcome this enigma by combining positional factors with other types of factors or mechanisms.

The second 'existential factor' generally related to collective belief is social interaction. Why do individuals share the same beliefs? Because, living generally not as hermits, they share the same ability to interact with others, and through these interactions, they have the same capacity to be influenced by others in the nature of their beliefs. There are of course numerous ways to conceptualize this social influence. In his classical *Laws of Imitation* (1890), G. Tarde uses the notion of imitation to describe one of its modalities. Defined as an 'interpersonal suggestion,' imitation acts as a social mechanism by which the individual's actions and beliefs are able to converge collectively in the same direction. Without necessarily endorsing the epidemiological approach of ideas developed by Sperber (1996) in the continuity of Tarde, sociologists frequently emphasize the importance of day-to-day interactions on the formation and diffusion of beliefs. It is well established that parents largely contribute, by explicit teaching and by example, to shaping their children's beliefs, moral values, and political preferences, at least until a certain age. Devout parents contribute to the reproduction of religious beliefs through their children (Myers, 1996; Kelley and De Graaf, 1997). But parents are only a small part of the interactional environment of children. Studies on primary and secondary forms of socialization describe the variety of interactions through which collective beliefs are not only transmitted but also produced and transformed. Kuhn (2012 [1962]) and Zuckerman (1977), in the tradition of the sociology of science, observe that the daily interaction between the masters and apprentices in science is essential for the production and transmission of normative and aesthetic beliefs. More generally, the importance of interaction has been analyzed for 'status beliefs,' that is, collective representations about inequality between people having

different kinds of occupation, education, age, race/ethnicity, or gender (Ridgeway et al., 1998). Interaction among individuals has a creative dimension: "People carry [their] status beliefs to subsequent encounters with individuals from the other category and, by acting on the beliefs, induce some of those others to take on the status beliefs as well. This creates a diffusion process that, under some structural conditions, will create roughly consensual (i.e., widely shared) status beliefs" (Ridgeway and Erickson, 2000: p. 581). If social influence is somehow inevitable, certain situations seem more likely to make people particularly receptive to it. Rydgren (2011) argues that social influence is at its strongest when two elements combine in a single situation: (1) a real uncertainty about the content of the belief and (2) a feeling of deviation from the belief held by most others in the immediate social surrounding. In this situation, the diffusion of beliefs depends heavily on the use of epistemic authorities and the tendency of individuals to harmonize their beliefs with those of significant others in order to reduce their own feeling of deviation.

This reference to feelings and emotions leads us to a third mode of explanations of collective beliefs, frequently combined with the two previous ones. If individuals or groups share the same beliefs it is because they are moved by the same collective feelings or the same emotional currents. In the famous *Traité de sociologie générale*, Pareto (1916) analyzes the social diffusion of the religions as the consequence of social 'feelings.' He affirms the importance of clearly separating the respective influence of 'derivations' – ideas, theories, theologies – and 'residues' – deep-rooted feelings. "The social value of the religions," Pareto writes, "depends very little on derivations, enormously on the residues. In several religions, there is a significant group of residues (…) which correspond to feelings of discipline, submission, hierarchy" (section 1854). For Pareto, the social actor wants to be convinced of the value of his or her passion, and produces derivations for this purpose. Religions or ideologies are just epiphenomenal expressions of dominant passions. If the Paretian model of collective beliefs remains generally ignored by contemporary sociologists, some of them do analyze the emergence and success of certain beliefs as the consequence of certain feelings, in particular relative deprivation feelings. As recalled by Merton (1964), the concept of relative deprivation comes from the study of the 'sentiments and attitudes' of American soldiers (Stouffer et al., 1949). The central premise of relative deprivation theory (Runciman, 1966) is that individuals or groups will feel deprived when their current circumstances are negatively compared to (1) one's own previous or anticipated future situation (self-referenced relative deprivation), (2) the (real or imagined) situation of members of one's in-group (e.g., friends and relatives), or (3) the (real or imagined) situation of members of external reference groups. Relative deprivation theory can be used to explain different kind of beliefs. How do personal experiences of economic recession affect the distribution of economic beliefs (Krahn and Harrison, 1992)? What accounts for the apparently 'universal' fact that women are more religious than men (Miller and Stark, 2002)? How do the new radical right-wing parties in Europe try to channel the feelings of anxiety and resentment of the social 'losers' of post industrialization processes (Rydgren, 2007)? Why are low socioeconomic status individuals more likely to seek God's will through prayer (Schieman, 2010)? To what extent are the representations of social inequality in the French population produced by comparison mechanisms (Galland et al., 2013)? In all of these studies, sociologists try to measure the social influence of feelings resulting from interpersonal comparison on the acceptance of religious, economic, or ideological beliefs.

A fourth sociological approach of collective beliefs can be briefly identified as culturalist. It proposes that belief is a piece of a wider sociocultural system that imposes itself on the social actors. Why do individuals share the same beliefs? Because living in the same collectivity, they are raised within the same dominant culture and thus tend to select their beliefs according to their degree of elective affinity with it. Moreover, beliefs are not independent from one another, but interconnected in a dominant cultural system. This culturalist approach is explicit in Sorokin's pioneer studies on *Social and Cultural Dynamics* (1937). Unlike others sociologists trying to explain belief by various states of the social structure – positional or interactional factors – Sorokin proposes to derive every aspect of shared knowledge from underlying 'culture mentalities.' Two 'pure types' of culture mentalities are identified: the *ideational* and the *sensate*. The former conceives of reality as 'nonmaterial' and defines human needs as primarily spiritual. The latter conceives of reality as only what can be perceived through the senses and defines human needs as primarily physical. Sorokin argues that what a given society regards as true or false, scientific or unscientific, is fundamentally conditioned by the long-term historical fluctuation of influence of these culture mentalities (Barber and Merton, 1963). If contemporary sociologists generally ignore the macro-sociohistorical perspective formulated by Sorokin, they still show strong interest in the relationship between culture and beliefs. In his study of public opinion on racial inequality, Bailey (2002) opposes Brazil to the United States. Why is there a Brazilian consensus – the majority of the population favors a structuralist representation – on the origins of racial inequality? According to Bayley, part of the answer comes from a specificity of the Brazilian culture. One important element that may separate Brazil from the United States is the lower salience of color as a marker of social belonging: "Brazil's color awareness responds to 'marca' or appearance, as opposed to "origem" or ancestry, the explicitly racial U.S. version. The difference between the two may be subtle, but not unimportant. (…) distinctions based on discrete racial identities may create caste-like or essentialist distinctions (…) But when socially constructed boundaries are porous or ambiguous, their significance may be reduced as markers of discrete, self-identifying social segments with diverging worldviews" (p. 429). Another recent example is sociological study of beliefs about illness and medicines. People differ not just in their beliefs about the nature and uses of medicines, but also in the degree to which they perceive themselves to be sensitive to side effects. In their study over a population of university students, Horne et al. (2004) show that "students who identified themselves as Asian in origin were more likely than students with a European origin to perceive medicines as intrinsically harmful. These findings support previous research, which

found that students who identified themselves as Asian were generally less satisfied with "Western" medical care compared with "Western" students" (p. 1312).

Finally, a fifth type of sociological explanation of collective beliefs focuses on the reasons or systems of reasons that social actors have to endorse their own beliefs. This approach to collective belief is generally combined with positional and interactional factors. It is generally described in terms of 'cognitive rationality' or 'ordinary rationality' (Boudon, 1994, 2010). Why do individuals share the same beliefs? Because they have the same capacity to develop a form of ordinary rationality and to adopt, in a deliberative manner or by simple aggregation, a common system of reasons. This cognitive explanation of beliefs is generally associated with Durkheim and Weber's classical writings on magic beliefs. "The acts motivated by magic, Weber writes (1922/1979), are acts at least relatively rational (…): they follow the rules of the experience even if they are not necessarily acts according to the means and ends." The same point is emphasized by Durkheim (1912/1995), in particular when he compares the rationality of traditional 'rites' and the rationality of modern 'techniques': "the rites which [the primitive] use to ensure the fertility of the ground (…) are not, to him, more irrational than are, to us, the technical processes used by our agronomists (…). The powers linked to these rites do not appear particularly mysterious. For those who believe in them, those forces are not more unintelligible than are gravity or electricity to a contemporary physicist." The explanatory strategy proposed by Weber and Durkheim invites the sociologist to reconstruct the set of reasons that the actor gives to himself to act. This cognitive approach is opposed to those involving the illusory nature of reasons or to those assuming that the behavior of the social actor is primarily emotional or mechanically forged by the cultural environment. Applied to various beliefs – the effectiveness of public policy on drug addiction (Bergeron, 1999), the existence of Santa Claus, the social resistance to Darwinism (Bronner, 2004, 2007), or paranormal beliefs that allege the existence of extraordinary beings and extraordinary phenomena (Renard, 2010) – the rationalist approach to collective beliefs follows four general principles summed up by Raymond Boudon (2011) in one of his last public conferences. These principles are that (1) ideas, and not interests, are the essential component of social action; (2) the causes of beliefs are consciously or meta-consciously present in the mind of the believer; (3) rationalization of ideas plays a central role in modern societies life; and (4) normative beliefs, just like descriptive beliefs, have their origin in ordinary rationality and are subject to a process of rationalization.

Robustness and Symmetry of Sociological Explanations

As shown by the examples discussed in the previous section, sociologists refer in the course of their studies to multiple factors or social mechanisms. However, which general conditions do sociologists need to respect in order to produce a convincing or robust explanation of collective beliefs? To conclude our discussion, four elementary conditions deserve to be briefly discussed.

First condition: *The sociological explanation of collective beliefs must be more than the translation of the phenomenon to explain a new idiom*. The sociologists of beliefs generally start from the identification of an enigmatic phenomenon. Why did the industrial bourgeoisie of the nineteenth century believe in the virtues of parliamentary monarchy (Marx)? Why do Zuni Indians adopt a representation of the world in seven categories (Durkheim)? Why were corpuscular and ondulatory theories of light widely accepted during the nineteenth century (Sorokin)? But it sometimes happens that their answers are only apparent. The methodological analysis of the theory of 'primitive mentality' thus shows that if the theory of Lévy-Bruhl (1922/1960) is not convincing anymore, this is essentially because it does not explain anything. The key concepts of this theory, Boudon emphasizes (1994), "only paraphrase the beliefs. They explain the confusion of the primitives between verbal associations and causal relations by the primitive's tendency to make this confusion, tendency whose reality is guaranteed by the fact that they do make it indeed." A similar point is made by Merton (1945) concerning Sorokin's theory. "It seems tautological, Merton writes, to say, as Sorokin does, that in a sensualist society and culture, the sensualist system of the truth based on the testimony of the sensory organs must prevail. Because he had already defined the sensualist mentality as one which conceives reality as being only what is perceived with the sensory organs." More recently, Cole (1996) pointed out that the analysis of the production of scientific beliefs by certain constructivist sociologists of sciences is primarily of a circular nature. These sociologists generally claim "that it is impossible to separate the technical from the social; that all science is inherently social. This turns their entire argument into a tautology. If science is inherently social, this means that the technical aspects of scientific discoveries by necessity must be determined socially. This is indeed the question we are examining."

Second condition: *The sociological explanation of collective beliefs must avoid ambiguous and/or occult concepts*. Sociologists use a great number of conceptual categories. Many proposals produced on the basis of the combination of these categories make clear and univocal sense; some, however, remain more ambiguous. For example, certain sociological explanations rest on an ambiguous concept of 'social,' or more precisely a confusion between the social and historical dimensions of a collective belief. To show, however, that a belief appears in a particular historical context is not the same as to demonstrate its social character. Laudan (1977) is right to observe that "the fact that certain assertions are contextual, that one adhered to it only to a certain time and in a certain place establishes neither that they are necessarily of social origin, nor even that they are opened to the sociological analysis." The sociological use of the concept of 'interest' constitutes another well-known example of ambiguity. This concept is sometimes used by sociologists of science in order to describe the origin of the prestige or credibility of scientific beliefs. In an under-determined situation, contemporary sociologists of science say, scientists choose between two concurrent theories the one that appears to conform to their best interests. However, how should we

conceive the exact nature of these interests? Are they material, symbolic, technical, or cognitive interests? As long as the concept of interest remains ambiguous, the sociologist cannot legitimately claim to explain the observed beliefs. In addition, following a Weberian principle, many sociologists closely associate the solidity of an explanation with the manner in which these explanations avoid using occult categories, that is, invisible forces – such as the Paretian concept of 'residue' or the 'primitive mentality' of Lévy-Bruhl – that determine the behaviors of the social actors. The methodological principle is simple and easily acceptable: the sociologist seeking to account for the origin of a collective belief may refer to the existence of an occult cause only insofar as she cannot explain this belief more easily, in particular by identifying her meaning. The obvious difference between the explanations of magic beliefs proposed on the one hand by Lévy-Bruhl and on the other by Durkheim and Weber seems to be directly linked to the application of this general principle by the latter.

Third condition: *The sociological explanation of collective belief must be compatible with observable facts*. This third condition can be interpreted in various ways. The first and simplest one consists of assuming that explanatory theories of scientific beliefs are not different from other scientific theories. They must not only dispose of various internal qualities (absence of circularity, precision, and so on) but also be able to be confronted with precise facts, and further still to resist this empirical test. These facts might be elementary observations. The observation, for example, of the persistence of the magic beliefs in Western societies seems hardly compatible with the assumption of a causal link between the magic beliefs and a 'primitive mentality' (Lévy-Bruhl). In the same way, the observation of the development of new religious movements in large cities openly contradicts the hypothesis that the contemporary process of urbanization is essentially a vector of disintegration of collective belief (Borhek and Curtis, 1975). These facts can also be more complex products of the interpretative reconstruction work done by the sociologist or anthropologist. When Horton (1993) argues, for example, against the tenants of symbolist theory of magic, he points out that this theory, for which magic beliefs are mainly the expression of a symbolic 'desire,' enters into flagrant contradiction with what the members of the traditional societies say about their own rituals: "(…) in denying the paramount importance of explanation, prediction and control as guiding aims of traditional African religious life, "symbolists" (…) are committing the cardinal interpretative sin of flouting the actor's point of view." Another way to interpret this third condition consists of associating the solidity of an explanatory theory with its capacity to give an account of other beliefs than the one for which it was initially elaborated. For example, is it possible to apply the explanatory scheme imagined by Durkheim and Weber for magic beliefs to other types of beliefs, such as ideological beliefs? The fact that this transposition is not only possible but brings an objective gain of intelligibility to the comprehension of ideological phenomenon (Boudon, 1986, 1989) demonstrates the real value of their general conception of the sociological explanation.

Sociologists frequently add to these three general conditions a fourth and final one: a condition known as the 'principle of symmetry.' This principle implies that the explanation of collective beliefs should be equally applied to phenomena of various natures. This last condition is not reducible to the conditions previously mentioned (the third one in particular) insofar as, to identify the nature of this plurality, it introduces a criterion of truth and falseness, rationality and irrationality. A sociological theory of collective beliefs is said to be symmetrical if it explains in the same terms true beliefs and false beliefs, rational beliefs and irrational beliefs. This principle, implicitly used by Sorokin (1937) or more recently explicitely by Boudon (2010), is directly opposed to the "a-rationality principle" according to which the sociological explanation of collective beliefs cannot be indifferent to the content of these beliefs. The interest of the principle of symmetry is twofold. From a methodological point of view, it requires the suspension of all evaluation related to the potential validity or invalidity of the analyzed collective belief. It thus represents a guarantee of neutrality. From the point of view of empirical research, it makes it possible to follow in unified and thus simplified terms the manner in which collective beliefs obtain social recognition, or conversely an absence of social recognition. The sociological use of this principle follows, however, two paths of unequal importance. The first, chosen by some sociologists of science, exists mainly to explain the scientific beliefs in terms of explanatory categories previously devoted to false beliefs. Linked to an exclusively causal approach of scientific belief production, this first use of the principle of symmetry has greatly contributed to the diffusion of a relativistic representation of science (Dubois, 2001). There is, however, another way to apply this principle. It consists of following the major intuition of the theory proposed by Weber and Durkheim: to seek behind all collective beliefs, true or false, socially validated or socially marginal, the influence of 'reasons,' objective and or subjective. Thusl, as Horton (1993) is reconstructing the limited rationality of certain African rituals, he defines the major nature of its explanatory project as elaborating "an explanatory framework that would deal 'symmetrically' with the traditional and the modern, the prescientific and the scientific."

Collective Efficacy and Crime

John R Hipp and James C Wo, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, we explore the literature on collective efficacy and crime, but pay attention to three major challenges that confront this literature, and researchers moving forward with the concept in studies of neighborhoods. These challenges are (1) precisely defining and measuring the concept of collective efficacy; (2) determining whether the notions of general cohesion and trust in neighborhoods are really components of collective efficacy, or determinants of it; and (3) whether neighborhood crime can have feedback effects on the level of collective efficacy.

Collective efficacy is a construct that originally comes out of the psychology literature and the writings of Bandura (1982, 1986). Although the psychology literature has explored the empirical effects of collective efficacy for various relatively small groups, arguably its largest impact on social science literature comes from the introduction of the concept to the neighborhoods and communities literature by Sampson et al. (1997). A voluminous literature that is largely sociological and criminological has explored the effect of collective efficacy on a number of community processes, including neighborhood crime rates.

In this article, we explore the literature on collective efficacy and crime, but pay attention to three major challenges that confront this literature, and researchers moving forward with the concept in studies of neighborhoods. These challenges are (1) precisely defining and measuring the concept of collective efficacy; (2) determining whether the notions of general cohesion and trust in neighborhoods are really components of collective efficacy, or determinants of it; and (3) whether neighborhood crime can have feedback effects on the level of collective efficacy.

A Brief History of the Concept of Collective Efficacy

Collective efficacy was initially introduced as a concept by Bandura (1982, 1986). Building on his notion of self-efficacy, Bandura noted that "Perceived collective efficacy will influence what people choose to do as a group, how much effort they put into it, and their staying power when group efforts fail to produce results" (Bandura, 1982: p. 143). His early consideration of the idea mostly conceptualized collective efficacy as a property of very large groups, such as nations and social movements (Bandura, 1986: pp. 449–453). This spawned a number of studies in the psychology literature in the 1990s and into the 2000s focusing on collective efficacy as a property of small groups, such as sports teams and work organizations (Zaccaro et al., 1995). Collective efficacy is conceptualized in this literature as a fundamentally group phenomenon that "… fosters groups' motivational commitment to their missions, resilience to adversity, and performance accomplishments …," and an emergent phenomenon in which "the locus of perceived collective efficacy resides in the minds of group members" (Bandura, 2000: p. 76)

The key twist in the trajectory of collective efficacy as a concept in the social sciences arguably came when Sampson and colleagues introduced the concept to the neighborhoods and communities literature. In what has since become a citation classic, their study in *Science* introduced the concept as a property of neighborhoods that might be able to reduce the level of violence (Sampson et al., 1997). This seminal study focused on neighborhoods in the city of Chicago, and proposed defining collective efficacy as the combination of a general sense of residents' willingness to provide informal social control along with high levels of trust and solidarity among residents. They argued for the plausibility of this broader conceptualization of collective efficacy compared to that developed in the psychology literature because "the willingness of local residents to intervene for the common good depends in large part on conditions of mutual trust and solidarity among neighbors" (Sampson et al., 1997: p. 919). The cross-sectional study indeed found that neighborhoods with higher levels of collective efficacy exhibited lower levels of violence (whether measured as perceived violence, violent victimization, or homicide events). This single study has fostered an army of subsequent research.

Sampson himself has further refined the concept of collective efficacy in subsequent work. In particular, he has argued that it is a concept that helps focus on social mechanisms, and moves away from a risk-factor approach (Sampson, 2006a,b). In this sense, he considers it a mediating variable between neighborhood structural characteristics and crime. He emphasizes that this concept is fundamentally about repeated interactions, which then impact expectations about the future (residents' beliefs about the actions of their fellow residents) (Sampson, 2006a,b). Sampson's work on collective efficacy and neighborhood crime can be seen in his recent book that chronicles the Project on Human Development in Chicago Neighborhoods (PHDCN) as a large study of neighborhoods in Chicago (Sampson, 2012).

Collective Efficacy: Challenges of Measurement

Measuring informal social control in neighborhoods is actually quite a challenging problem. The challenge is that informal social control activity is only on display in moments in which there are challenges to the social order. This potential response on the part of residents is typically hypothetical, or *latent*.

Thus, attempting to measure the behavior of informal social control is difficult because of its rarity. This is both a methodological challenge (for measurement) as well as a theoretical challenge. More commonly, studies have relied on questions that are hypothetical about how the respondent would behave in a particular instance (Warner, 2007). In the case of studies measuring collective efficacy, the hypothetical questions ask respondents how they believe *their neighbors* would behave in various situations (Sampson et al., 1997). Answering such questions will sometimes be difficult if residents have never seen their neighbors be confronted by situations requiring informal social control behavior and require them to speculate on the answer. This speculation is particularly likely in neighborhoods with low levels of crime or disorder (St. Jean, 2007: p. 211). Besides these issues around uncertainty is the challenge of measuring a group concept by surveying individuals. This issue remains unresolved in the literature, as Zaccaro et al. (1995) note, "… a more useful approach to defining collective efficacy is to consider both judgments of members' abilities and perceptions of how well group members work together in achieving collective outcomes" (p. 309).

Other approaches have instead attempted to measure collective efficacy using behavioral measures. For example, one study suggested that parental monitoring may represent collective efficacy in action (Rankin and Quane, 2002). Another study used the presence of registered voters as a proxy for the collective efficacy in a streetblock (Weisburd et al., 2012). One unique and clever approach to measuring collective efficacy in neighborhoods constructed a website that allowed residents of neighborhoods to start webpages, and then assessed the usage of the pages as one measure of collective efficacy (Hampton, 2010). An interesting finding was that there were two extremes of neighborhoods that generated such webpages – new middle-class suburban neighborhoods and truly disadvantaged neighborhoods – suggesting that such a measure may be tapping some different processes than the more conventional measures of collective efficacy.

Distinguishing between Cohesion and Informal Social Control: One Construct, or Causally Related?

Although Sampson and colleagues defined collective efficacy in neighborhoods as being a combination of both cohesion/trust and expectations of informal social control, there is debate about this strategy. It is worth noting that the psychology literature has typically conceived of cohesion and collective efficacy as two separate constructs, which may separately impact one another in a causal fashion (Zaccaro et al., 1995). Empirical evidence in the communities and crime literature suggests that these may indeed be distinct constructs in many locations. Horne (2004) notes that the two measures are not always highly correlated and that high levels of cohesion do not necessarily increase norm enforcement. A study in Chicago suggested that informal social control attitudes mediated the relationship between neighborhood cohesion and crime (Rhineberger-Dunn and Carlson, 2011). A study of Tianjin, China found a correlation of just 0.43 between neighborhood cohesion and informal control, suggesting that they are in fact distinct constructs (Zhang et al., 2002). A study that split cohesion and expectations of informal social control found that while cohesion had a negative effect on perceived incivilities in the neighborhood, expectations of informal social control had no impact (Reisig and Cancino, 2004). A study of Mesa, AZ found minimal factor analysis evidence for combining these two constructs, and also found that only cohesion had a negative effect on violent crime when both were included in the model simultaneously (Armstrong et al., 2010). A study of Brisbane neighborhoods using a confirmatory factor analysis strategy also found no evidence for combining these two constructs; furthermore, this study used measures capturing collective efficacy for three distinct tasks, and all of them were distinct from a measure of cohesion (Wickes et al., 2013). Another study measured neighborhood attachment rather than cohesion, and found that higher levels of attachment led to higher levels of expectations of informal social control (Burchfield, 2009; Silver and Miller, 2004).

A key assumption of the neighborhood collective efficacy literature is that these norms and attitudes within a neighborhood that lead residents to perceive higher levels of collective efficacy then translate into actual higher levels of informal social control behavior. Thus, "Social movements and collective efficacy theory share a common orienting framework – a focus on the mobilization of action for an intended purpose" (Sampson et al., 2006: p. 4). As Steenbeek and Hipp (2011: p. 839) noted: "expectations that others will intervene (potential social control) need not necessarily result in people actually intervening more (actual social control behavior), even though this is implicitly assumed by social disorganization theory." However, only a few studies have addressed this question empirically, and the evidence so far appears somewhat weak. For example, one study in the Netherlands did not have a robust measure of collective efficacy, but did use longitudinal data to test and find that the potential for social control (measured by a single question asking about residents' willingness to improve the neighborhood) in fact did *not* increase social control behavior two years later (Steenbeek and Hipp, 2011). A study of neighborhoods in Brisbane focused on residents who reported a high level of disorder in the neighborhood, and found that higher levels of reported collective efficacy did not in fact lead to more actual informal social control behavior (Wickes et al., 2012). Instead, this study found that higher levels of neighboring increased the likelihood of engaging in informal social control behavior. As another example, a study using an experimental design concluded that norms are more likely to be enforced when there are benefits that increase social interaction, which suggests that cohesion might be more important for fostering action than residents' perceptions of informal social control potential (Horne, 2004).

Studies Assessing the Consequences of Collective Efficacy in Neighborhoods

A number of studies have assessed the cross-sectional relationship between neighborhood collective efficacy and crime, with studies almost always finding a negative relationship. The seminal study of Chicago found such an effect (Sampson et al., 1997), and subsequent studies in Chicago have also detected this negative relationship (Sampson and Raudenbush, 1999; Morenoff et al., 2001;

Schreck et al., 2009). This relationship has also been detected in other locations, including Stockholm (Sampson and Wikstrom, 2008), Los Angeles (Burchfield and Silver, 2013), Tianjin, China (Zhang et al., 2007), and Brisbane (Mazerolle et al., 2010). A challenge with some cross-sectional studies is the use of victimization reports as the outcome measure; in such studies the independent variable of collective efficacy is measured at one point in time but the dependent variable of victimization is assessed based on incidents that occurred during the previous year, introducing a temporal problem.

Studies have also assessed the relationship between neighborhood collective efficacy and various other outcomes, typically in cross-sectional designs. For example, studies in Chicago have found a negative relationship between collective efficacy and partner violence (Browning, 2002; Wright and Benson, 2011), risky sexual behavior by adolescents (Browning et al., 2008), sexual initiation by adolescents (Browning et al., 2005), self-control by children (Gibson et al., 2010), self-rated physical health (Browning and Cagney, 2002), and mortality during a heat wave (Browning et al., 2006). However, one study in Chicago found countervailing evidence, as impulsivity had an even stronger effect on offending in neighborhoods with high levels of collective efficacy (Zimmerman, 2010). This negative relationship between collective efficacy and various outcome measures has also been detected in other cities, including such outcomes as substance use by adolescents (Erickson et al., 2012) and bullying in school (Williams and Guerra, 2011). A longitudinal study found that collective efficacy increased authoritative parenting, which reduced delinquency among adolescents; it also found that authoritative parenting had the strongest effect in high collective efficacy neighborhoods (Simons et al., 2005). One study explored how school social controls were weakened in low collective efficacy neighborhoods when measuring the outcome of suspensions and arrest (Kirk, 2009). However, a study in England only found a negative relationship between collective efficacy and adolescent delinquency in economically deprived neighborhoods, but not in more economically advantaged neighborhoods (Odgers et al., 2009).

Sampson (2006a,b) points out that a distinction can be made between a theory of neighborhood crime rates and one of individual development, which is a distinction between enduring effects and situational effects. In this framework, collective efficacy may be more appropriately considered a situational theory. Indeed, a study in Chicago found no relationship between collective efficacy and violence committed by specific racial group members (Sampson et al., 2005), suggesting that collective efficacy may operate as a situational factor impacting crime events, and not as a factor creating offenders. Other research has found that robbers are less likely to offend in a high collective efficacy neighborhood, again emphasizing the role of collective efficacy in situational theories (Bernasco and Block, 2009).

The Possible Feedback Effect from Neighborhood Crime to Collective Efficacy

Relatively understudied is the possibility that crime may have a feedback effect on neighborhood-level collective efficacy. This feedback possibility has been discussed by Sampson (2006a,b) and Sampson and Raudenbush (1999). Indeed, St. Jean (2007: p. 211) argued that research needs "to pay close attention to the reciprocal relationship between high collective efficacy and low crime rates" because "… under conditions of low crime, neighbors are quite likely to report high estimates of trust and solidarity among themselves, and of the willingness of others to intervene" even though we do not know if they will actually intervene.

Nonetheless, studies have rarely accounted for this likely endogenous relationship between collective efficacy and crime, and instead often simply assume a one-directional causal relationship from collective efficacy to crime. One study tested and found such a negative feedback effect from crime to collective efficacy in a cross-sectional analysis utilizing instrumental variables (Sampson and Raudenbush, 1999). A cross-sectional study of neighborhoods in Mesa, AZ also used instrumental variables and found a negative feedback effect from crime to collective efficacy (Armstrong et al., 2010), and a cross-sectional study of 100 urban neighborhoods found a similar feedback effect on residents' expectations of informal social control with the use of instrumental variables (Bellair, 2000). Occasional research has ignored the possible effect of collective efficacy on crime and simply tested the reverse posited causal path; for example, one study found that violent crime had a negative relationship with neighborhood collective efficacy (Duncan et al., 2003), whereas another study found that violent crime was associated with lower levels of trust in a neighborhood (Garcia et al., 2007).

Social Networks and Collective Efficacy

Another thorny theoretical and methodological issue concerns disentangling the effects of the social network of residents in a neighborhood, the level of cohesion, and the level of collective efficacy. Besides the considerable conceptual overlap in these concepts, there is also a considerable overlap in how they operate in neighborhoods. An additional challenge is that actually measuring the social network of ties among residents in a neighborhood is extremely difficult, and studies are typically constrained to proxying neighborhood ties by asking a sample of residents to report how many neighbors they know. Such measures are simply estimates of mean degree in a neighborhood and do not capture any richer information about the full network (Bursik, 1999). Therefore, one recent study adopted the novel approach of *simulating* the networks existing in neighborhoods based on certain well-understood properties of network tie formation, and detected strong negative relationships between various structural network measures and crime in micro-units (Hipp et al., 2013).

Beyond these measurement challenges, there are at least three perspectives on how the social network of a neighborhood and the level of collective efficacy might be related: (1) a dense network of ties in a neighborhood leads to more collective efficacy; (2) a dense network of ties is necessary for, but not sufficient for, neighborhood collective efficacy; (3) there is no consistent relationship between the network of ties and collective efficacy. The first perspective builds on the insights of systemic theory and the importance of the network of ties among residents for fostering behavior (Kasarda and Janowitz,

1974). It is difficult to conceive of a neighborhood with high levels of cohesion but lacking dense social networks. Indeed, a study focusing on the actual provision of informal social control behavior in response to observed problems among residents of Brisbane neighborhoods found that the most important predictor of such behavior was a higher density of neighborhood ties, and not assessments of collective efficacy (Wickes et al., 2012).

In the second perspective, social networks are a necessary, but not sufficient, characteristic for a neighborhood to develop collective efficacy. Sampson (2006a,b) argues that the relationship between dense networks and informal social control capability in neighborhoods is more tenuous, and that in some neighborhoods dense ties can actually inhibit social control behavior. Empirically, Sampson (2006a,b) showed that indicators of friendship ties loaded on a different factor than the collective efficacy indicators. In short, networks may provide social capital for offenders, as well as others in the neighborhood (Browning et al., 2004). For example, Browning (2009) suggested that dense networks can bring together offenders and conventional residents, which then weakens the effect of collective efficacy in this 'negotiated coexistence' model.

In the third perspective, there is enough inconsistency in how neighborhood networks and collective efficacy relate that no pattern can be distinguished. For example, a study using in-depth interviews in two high collective efficacy neighborhoods found that strong social ties were not necessary: instead symbols of community and collective representations generated higher levels of collective efficacy (Wickes, 2010). Notably, this same study noted that key neighborhood institutions and organizations were crucial for responding to problems, suggesting that formal organizations may be understudied in this literature.

Theoretical Extensions of the Collective Efficacy Construct

There have been various theoretical extensions to the collective efficacy model in recent years. One important direction is recent research that has emphasized the importance of the *task-specific* nature of collective efficacy. Just as self-efficacy is in respect to a specific task, likewise collective efficacy is fundamentally in respect to a specific task. Despite the importance of the task-specific nature of the collective efficacy construct, nearly all studies in the communities and crime literature have tested it as a unitary phenomenon. Thus, researchers often refer to the 'collective efficacy' of a neighborhood as if it is a unitary phenomenon, rather than the 'collective efficacy regarding X specific task.' Not only does this lose the conceptual richness of the construct, but it also increases the risk of allowing the concept of collective efficacy to slide into a measure of 'everything good' about a neighborhood, a charge sometimes leveled against the concept of social capital (Portes, 1998). In response to this lacuna, a study of Brisbane neighborhoods measured collective efficacy for three distinct tasks and not only found important differences in the determinants of each of these, but also found that these tasks were distinct from the more global construct of cohesion and trust (Wickes et al., 2013). Thus, making a distinction between residents' collective efficacy regarding addressing violence in the neighborhood, vs. addressing confronting misbehaving children, and vs. addressing political/civic matters demonstrated that neighborhoods and individuals differed regarding these particular tasks.

There are also other developments. In an example of theoretical integration, some research has attempted to integrate the legal cynicism literature with collective efficacy. For example, one study found that collective efficacy mediated the relationship between highly cynical neighborhoods and the probability of arrest (Kirk and Matsuda, 2011). Another strand of research has developed the notion of 'street efficacy' for residents. In this view, adolescents with high street efficacy choose the streets that they frequent in order to avoid violence, which has consequences for the environments in which they find themselves (Sharkey, 2006). Another research strand focuses on how perceptions of collective efficacy might impact the perceptions of other neighborhood characteristics – even the neighborhood's boundaries. For example, a study suggested that residents in neighborhoods with higher levels of collective efficacy perceive their neighborhoods to be larger in size (Coulton et al., 2013).

Conclusion

Collective efficacy is clearly a hugely important concept in the communities and crime literature, which has spawned considerable theoretical and empirical excitement. There is a large body of literature that has detected a negative relationship between the level of collective efficacy in a neighborhood and the crime rate. However, important directions need to be explored. One important direction is distinguishing whether collective efficacy operates differently in high versus low disorder neighborhoods. St. Jean argued that collective action is only necessary if the block is attractive to offenders: if the block is not desirable to offenders, there will not be crime regardless of what residents do (St. Jean, 2007: p. 164). A second important direction is longitudinal research of this relationship. Given the very plausible expectation of a feedback effect from neighborhood crime to perceptions of collective efficacy, as well as the suggestive evidence from cross-sectional studies, there is clearly a strong need for longitudinal research to determine whether the collective efficacy and crime relationship is robust.

Abstract

This article provides an analytic overview of scholarly work on the concept of collective identity by considering its conceptualization and various empirical manifestations, the analytic approaches informing its discussion and analysis, and a number of theoretical and empirical issues, including a synopsis of the symbolic means through which collective identity is expressed and asserted. Although the scholarly roots of the concept can be traced to classical sociologists such as Marx and Durkheim, and more recently to the midcentury work of scholars such as *Erik Erickson* and *Erving Goffman*, it was not until the latter quarter of the past century that the concept generated an outpouring of work invoking the concept directly or referring to it indirectly through the linkage of various collectivities and their identity interests via such concepts as *identity politics*, *contested identities*, *insurgent identities*, *nationalism*, *imagined communities*, *identity movements*, and even *social movements* more generally. Conceptually, the essence of collective identity resides in a shared and interactive sense of 'we-ness' and 'collective agency.' Although the concept is distinguished analytically from both *personal identity* and *social identity*, the three types of identity clearly overlap and interact. Empirically, collective identity can surface in a variety of contexts, although the preponderance of research has focused on its connection to *gender*, *ethnicity*, *religion*, *nationalism*, and particularly *social movements*. Analytically, collective identity has generally been discussed from a primordial, structural, and/or constructionist standpoint. Primordial and structural approaches are discussed as variants of *essentialism*, which is contrasted to *constructionism*. Among other things, constructionism focuses attention on the *symbolic expression* and maintenance of collective identities.

If key concepts or expressions can be identified that function to capture the animating spirit of different epochs, then certainly one candidate concept for the last 40–50 years is the concept of collective identity. Indeed, it is a concept that came of age in the latter part of the past century, as reflected in the outpouring of scholarly work invoking the concept directly or referring to it indirectly through the linkage of various collectivities and their identity interests via such concepts as identity politics, contested identities, insurgent identities, and identity movements. This article provides an analytic overview of scholarly work on the concept by considering, in order, its conceptualization, its various empirical manifestations, the analytic approaches informing its discussion and analysis, and several unresolved theoretical and empirical issues.

Conceptualization

The concept of collective identity, just as the base concept of identity, is rooted in the observation that interaction between two or more sets of actors minimally requires that they be situated or placed as social objects. To do so is to announce or impute identities. Hence, interaction among individuals and groups, as social objects, is contingent on the reciprocal attribution and avowal of identities. This process holds for both individuals and collectivities, and it probably has always been a characteristic feature of human interaction. To note this is not to ignore the sociological truism that the issue of identity becomes more problematic and unsettled as societies become more structurally differentiated, fragmented, and culturally pluralistic (Castells, 1997; Giddens, 1991). But historical variation in the extent to which matters of identity are problematic does not undermine the double-edged observation that the reciprocal imputation and avowal of identities is a necessary condition for social interaction and that identities are thus rooted in the requisite conditions for social interaction.

Delineating the interactional roots of identities does not explain what is distinctive about collective identity, as there are at least three conceptually distinct types of identity: personal, social, and collective. Although they often overlap, one cannot be inferred from the other. Hence, the necessity of distinguishing among them.

Social identities are the identities attributed or imputed to others in an attempt to situate them in social space. They are grounded typically in established social roles, such as 'teacher' and 'mother,' or in broader and more inclusive social categories, such as gender categories or ethnic and national categories, and thus are often referred to as 'role identities' (Stryker, 1980) and 'categorical identities' (Calhoun, 1997). Whatever their specific sociocultural base, social identities are fundamental to social interaction in that they provide points of orientation to 'alter' or categorize 'other' as a social object.

Personal identities are the attributes and meanings attributed to oneself by the actor; they are self-designations and self-attributions regarded as personally distinctive. They are especially likely to be asserted during the course of interaction when other imputed social identities are regarded as contradictory, as when individuals are cast into social roles or categories that are insulting and demeaning (Snow and Anderson, 1987). Thus, personal identities may derive from role incumbency or category-based memberships, but they are not necessarily comparable since the relative salience of social roles or category membership with respect to personal identity can be quite variable.

Just as social and personal identities are different yet typically overlapping and interacting constructs, such is the relationship between collective and social and personal identities. Although there is no consensual definition of collective identity, discussions of the concept invariably suggest that its essence resides in a shared sense of 'one-ness' or 'we-ness' anchored in real or imagined shared attributes and experiences among those who comprise the collectivity and in relation or contrast to one or more actual or imagined sets of 'others.' Embedded within the shared sense of 'we' is a corresponding sense of 'collective agency.' This latter sense, which is the action component of collective identity, not only suggests the possibility of collective action in pursuit of common interests, but even invites such action. Thus, it can be argued that collective identity is constituted by a shared and interactive sense of 'we-ness' and 'collective agency.' This double-edged sense can be culled from classic sociological constructs such as Durkheim's 'collective conscience' and Marx's 'class consciousness,' but is reflected even more clearly in most conceptual discussions of collective identity, although the agentic dimension is sometimes implied rather than directly articulated (e.g., Castells, 1997; Cerulo, 1997; Jasper and Polletta, 2001; Jensen, 1995; Melucci, 1989, 1995).

A common theme running throughout a segment of the literature on collective identity is the insistence that collective identity is, at its core, a process rather than a property of social actors. Such work acknowledges that collective identity is 'an interactive and shared definition' that is evocative of "a sense of 'we,'" but then highlights the process through which social actors recognize themselves as a collectivity, contending that this process is more vital to conceptualizing collective identity than any resultant product or property (e.g., Melucci, 1989: pp. 34, 218, passim). Few scholars would take exception with the importance of the process through which collective identities develop, but it is both questionable and unnecessary to contend that the process is more fundamental than the product to understanding the character and functionality of collective identity. Not only is the product or 'shared we' generative of a sense of agency that can be a powerful impetus to collective action, but it functions, as well, as the orientational identity for other actors within the field of action. More concretely, it is the constructed social object to which the movement's protagonists, adversaries, and audience(s) respond (Hunt et al., 1994), and which, in turn, may have implications for the operation of its organizational carrier, affecting the availability and character of allies, resources, and even tactical possibilities (Jensen, 1995).

The initial projected collective identity may be short lived and transient, subject to modification and even transformation during the course of ongoing collective (inter) action. Whatever the character of the collective identity, the underlying collective interaction often occurs through participation in social groups. For example, Jones' (2011) work on collective identity building in a mixed-race student organization highlights how identity formation can be a group process involving strategies to achieve a sense of belonging and cohesion through the micropractices that are essential to group formation. And, these emerging collective identities can, reflexively, shape the personal and social identities of group members.

Collective identities are distinguished from social and personal identities in several ways. First, collective identities may or may not be embedded in existing social identities, since they are often emergent and evolving rather than firmly rooted in prior social categories. This is often the case with the collective identities that emerge in the course of dynamic social protest events (for illuminating examples, see Calhoun's and Zhao's accounts of the Chinese student movement of 1989) or over time in relation to larger historical changes (e.g., Roth's work on the emergence of collective identity in the US women's movement 2008). Second, the collective, shared 'sense of we' is animating and mobilizing cognitively, emotionally, and sometimes even morally. The shared perceptions and feelings of a common cause, threat, or fate that constitute the shared 'sense of we' motivate people to act together in the name of, or for the sake of, the interests of the collectivity, thus generating the previously mentioned sense of collective agency. That potential inheres within social identities, but they typically function more like orientational markers as the routines of everyday life are negotiated. When they are activated or infused affectively and morally, it is arguable that they have been transformed into collective identities. Third, the emergence and operation of collective identities mean that other social identities have subsided in relevance and salience for the time being. In other words, collective identities, when they are operative, generally have claims over – not so much normatively as cognitively and emotionally – other identities in terms of the object of orientation and character of corresponding action. Examples abound, as observed frequently in the case of many protest gatherings, gripping fads, joyous and celebratory sports crowds, and the concerted campaigns and actions associated with social movement activism. Fourth, while collective identities and personal identities are obviously different, they are still very much interconnected in the sense that collective identities are predicated, in part, on constituents' embracement of the relevant collective identity as a highly salient part of their personal identity and sense of self (Gamson, 1991). And finally, while the attribution or avowal of all identities is interactionally contingent, collective identities tend to be more fluid, tentative, and transient than either categorically based social identities or even personal identities.

Empirical Manifestations

Empirical manifestations of collective identity can vary in a number of significant ways. One important axis of variation is the size of the collectivity, and the corresponding scope of its claims. If the essence of collective identity resides in a sense of 'we-ness' associated with real or imagined attributes in contrast to some set of others, then it follows that collective identities can surface among almost any grouping or aggregation in a variety of contexts. These could range from relatively small cliques and gangs, to sports fans and celebrity devotees, to laborers and occupational groupings, to neighborhoods and communities, and even to broader categories such as sexual and gender categories, religions, ethnic groups, and nations. The preponderance of empirical research on collective identity has focused on the last, more inclusive set of categories – sexuality and gender, religion, ethnicity, and nationality.

Illustrative is Ward's (2008) research on gay and lesbian identity within organizations; Wilkes' (2006) analysis of the importance of collective identity for mobilization among Indigenous peoples; Cornell and Hartmann's (1998) overview of the construction of ethnic and racial identities in the modern world; and Anderson's (2006) and Calhoun's work on nationalism, which the latter defines, in part, as one "way of constructing collective identities" (1997: p. 29).

Social movement mobilizations also tend to be both generative of and dependent on collective identities (e.g., Bernstein, 2005; Gamson, 1991; Hunt et al., 1994; Jasper and Polletta, 2001; Melucci, 1989; Snow and McAdam, 2000; Van Stekelenberg, 2013). In fact, one of the most consistent findings in this area of research is that identifying with a social movement cause or collectivity enhances the probability of participation for individuals across a variety of movements (Corrigall-Brown et al., 2009; Dixon and Roscigno, 2003; Liss et al., 2004).

Although collective identities can congeal in various aggregations and contexts, they appear not to do so on a continuous basis historically. Instead, their emergence and vitality appear to be associated with conditions of sociocultural change or challenge, socioeconomic and political exclusion, and political breakdown and renewal, thus suggesting that they cluster historically in social space. The past 50 years has generally been regarded as one such period of collective identity effervescence and clustering, with some scholars characterizing this period in terms of identity crises and collective searches for identity (e.g., Castells, 1997; Gergen, 1991; Giddens, 1991; Klapp, 1969). In *The Power of Identity*, Castells captures both this characterization and the kinds of conditions thought to be associated with the various manifestations of collective identity during this period:

> Along with the technological revolution, the transformation of capitalism, and the demise of statism, we have experienced, in the last quarter of the century, the widespread surge of powerful expressions of collective identity that challenge globalization and cosmopolitanism on behalf of cultural singularity and people's control over their lives and environment. (Castells, 1997: p. 2)

Analytic Approaches

To note that expressions of collective identities cluster historically according to the conjunction of various social conditions does not specify the character or content of the emergent collective identities. This issue has been addressed from the vantage point of three contrasting perspectives: primordialism, social structuralism, and social constructionism.

Both the primordialist and structuralist views can be construed as variants of an overarching essentialist perspective which posits that a collectivity's identity basically flows naturally from some underlying set of characteristics, often reduced to a single determinative attribute regarded as the collectivity's 'defining essence.' From the primordialist point of view, the defining characteristic is typically an ascriptive attribute, such as race, gender, or sexual orientation, or sometimes a deep, underlying psychological or personality disposition.

From a structuralist perspective, the critical characteristic is typically a kind of master social category implying structural commonality, such as social class, ethnicity, or nationality; a set of relational ties or networks suggesting structural connectedness; or a mixture of both. Individuals who are similarly situated structurally, such that they are incumbents of similar roles, work in similar enterprises, are linked to the same social networks, or are members of the same social class, religion, or ethnic group, are presumed to have a shared collective identity or at least be candidates for such.

The constructionist perspective, in general, rejects both the primodialist and structuralist variants of the essentialist argument, seeing the presumed link between identities and their ascriptive or structural moorings as being more indeterminate than postulated. Instead, attention is shifted to the construction and maintenance of collective identities. Collective identities are seen as invented, created, reconstituted, or cobbled together rather than being biologically preordained or structurally or culturally determined.

Assessment of the three perspectives in terms of their relative analytic utility for explaining the character and content of collective identities reveals considerable support for the constructionist thesis. This may be due in part to the currents of fashion, influenced by the winds of multiculturalism, postmodernism, and identity politics, but it is also due, more importantly, to other factors. One is that the hypothesized link between identities and the primordial attributes or structural categories in which they are presumably anchored is too mechanistic. In its hard version, it is contradicted by the sociological observation that people are often members of the same categories or groups in different ways and with varying degrees of commitment and identification, thus suggesting that inferring correspondence between personal, social, and collective identities solely on the basis of primordial or structural categories is empirically suspect. Additionally, the claims of primordialist and structuralist arguments do not fare well when confronted with the observation that people generally have multiple identities (e.g., family, work, leisure, gender, ethnic, religious, political, and national) that are differentially invoked or avowed depending on their relative salience and their situational pervasiveness. Salience refers to the relative importance of an identity in relation to other identities (Stryker, 1980); pervasiveness or comprehensiveness refers to the situational relevance or reach of any particular identity and the corresponding degree to which it organizes social life, including collective action (Cornell and Hartmann, 1998; Snow and McAdam, 2000). Given the fact that increasing numbers of individuals live in a world in which they are the carriers of multiple and often conflicting identities, what determines any particular identity's relative salience and pervasiveness, and thus the influence of its claims, vis-à-vis others? Clearly such matters are not determined solely by an identity's primordial roots or structural footing. And finally, much of the empirical evidence is consistent with the constructionist argument. Two highly evocative examples include Trevor-Roper's (1983) account of the retrospective invention of the distinctive Highland culture and tradition so redolently associated with all of Scotland, and James' parallel conclusion, based on extensive archeological and archival research, regarding the origins of the modern Celts:

> …the idea of a race, nation or ethnic group called Celts in Ancient Britain and Ireland is indeed a modern invention. It is an eighteenth- and nineteenth-century reification of a people that never existed, a factoid…assembled from fragments of evidence drawn from a wide range of societies across space and time. This reification served the interests of a range of cultural expectations, aspirations, and political agendas – and still does. (James, 1999: p. 136)

Such conclusions should not be read as unequivocal refutations of the primordialist and structuralist arguments, since constructed identities are not fabricated whole cloth but typically knit together by drawing on threads of past and current cultural materials and traditions, structural arrangements, and even primordial attributes. These materials and attributes constitute the kinds of things from which collective identities – particularly ethnic, religious, and national ones – are fashioned, and thereby function, in varying degrees, to constrain the construction process. With this in mind, it is advisable to consider these theories as not competing but, instead, as potentially complementary. This complementarity is illustrated in Eriksen's work on the emergence of nationalism (2004) which shows that both kinship (ethnicity) and place (territory) – basic elements of the more traditional primordial and structuralist perspectives – are important elements in the construction of a national identity.

Interpretative constraint also may be exercised by the institutional contexts and relations of power in which contestants are embedded (Castells, 1997; Jensen, 1995). Additionally, analyses of the relationship between collective identity and participation in social movements repeatedly point to the experience of collective action itself as a fertile seedbed for the generation of collective identities (Calhoun, 1991; Fantasia, 1988; Melucci, 1989) providing what Dufour and Giraud (2007) describe as "collective identity moments." Thus, while collective identities are undeniably constructed, they rarely are constructed *carte blanche*; rather, they typically are forged not only with the materials suggested by the primordialist and structuralist perspectives, but with and through the experience of collective action itself.

Theoretical and Empirical Issues

Relevant to a thoroughgoing understanding of collective identity, whatever its empirical locus, are several theoretical and empirical issues that require more careful consideration than often accorded.

Identity Work (the Expression of Collective Identities)

Fundamental to understanding collective identity, particularly from a constructionist standpoint, are the processes through which it is created, expressed, sustained, and modified. These processes have been conceptualized as variants of 'identity work,' which encompasses the range of activities people engage in, both individually and collectively, to signify and express who they are and what they stand for in relation or contrast to some set of others (Einwohner, 2013; Schwalbe and Mason-Schrock, 1996; Snow and Anderson, 1987; Snow and McAdam, 2000). In some times and contexts, identity work can be more difficult than at other times and in other contexts. In essence, the 'identity workload' can be heavier (Reger et al., 2008). At its core, identity work is the generation, invocation, and maintenance of symbolic resources used to bound and distinguish the collectivity both internally and externally by accenting commonalities and differences (Schwalbe and Mason-Schrock, 1996; Taylor and Whittier, 1992).

While these collective movement identities are often oppositional, recent work cautions that the line between 'us' and 'them' is not always clear and impermeable (Reger et al., 2008). Ghaziani's (2011) study of gay identity over time illustrates the dynamic relationship between movement collective identities and 'others,' arguing that we live in a 'post-Gay' society in which the gay and lesbian community has moved from an oppositional (us versus them) identity to an inclusive (us and them) one. This work highlights how collective identities are constructed and reconstructed over time.

Symbolic resources include the interpretive frameworks (or frames), avowed and imputed names, and dramaturgical codes of expression and demeanor (e.g., particularistic styles of storytelling, dress, adornment, and music) that are generated and employed during the course of a collectivity's efforts to distinguish itself from one or more other collectivities. Hunt and Benford (2004) argue that "fundamentally, collective identities are *talked* into existence … personal and collective identities shape and are shaped by collective action and the subsequent identity talk" (p. 445). In addition to identity talk, groups use particular songs and styles of music that invite participation and that are politically and emotionally evocative, such as 'We Shall Overcome' (Eyerman and Jamison, 1998; Roy, 2010); key words and slogans that function in a similar fashion, such as '*Liberte*, *Fraternite*, and *Egalite*' and 'Workers of the World Unite'; and systems of gestures and signs, such as the raised clinched fist and the peace sign, that function similarly to the tradition of heraldry. These and other symbolic resources function as boundary markers of collective differentiation, distinguishing insiders from outsiders, or protagonists from antagonists, in a fashion that heightens awareness of in-group commonalities and connections and out-group differences. Together they congeal into a kind of 'semiotic bricolage' (Schwalbe and Mason-Schrock, 1996) that gives symbolic substance to the claimed distinctive 'we,' and it is largely through this bricolage that collective identity is expressed and known publicly. While the boundary-making and -maintenance functions of these symbolic resources, or bricolage, are widely acknowledged, what accounts for the differential resonance or carrying power of different symbolic markers is less well understood.

The Problem of Identity Correspondence

A not uncommon problem with analyses of collective identity is the tendency to reify the collective identity, and thus take-for-granted the link between the individuals that make-up the collectivity and the shared, overarching identity. This gloss is particularly troublesome in light of the observation that people typically have multiple identities that vary in salience and pervasiveness. Thus, how is any particular collective identity reconciled with other identities adherents possess? Such

questions allude to what has been referred to as the problem of 'identity correspondence' – the alignment or linkage of personal and collective identities (Snow and McAdam, 2000).

One general answer is that this alignment "is accomplished by enlarging the personal identities of a constituency to include the relevant collective identities as part of their definition of self" (Gamson, 1991: p. 41). But what are the processes through which prospective adherents come to embrace the relevant collective identity, such that personal and collective identities are correspondent or congruous? Two broad processes have been suggested: identity convergence and identity construction.

Identity convergence refers to the union of personal and collective identities when both are congruent, such that an extant collectivity provides a venue for an individual to act in accordance with his or her personal identity. The analytic problem is not one of identity construction or transformation, but one of linkage or bridging and the identification of the mechanisms that facilitate the convergence. A number of such mechanisms have been identified. One operates at the organizational level, entailing the occasional appropriation of existing solidary networks by movement organizations (Snow and McAdam, 2000); the other mechanisms are variants of rational choice processes. One is based on a 'tipping' or 'threshold' model, which posits that collective identities are assumed by individuals when the perceived actions of others reach a point that suggests that the payoffs for adopting, or at least acting in accordance with, the collective identity outweigh doing otherwise. Illustrative is the contention that such tipping points played a critical role in explaining language and identity shifts among Russian-speaking immigrants 'beached' in four of the republics of the former Soviet Union (Laitin, 1998). A related mechanism is the existence of intergenerational investments in personal identities that may have implications for the embracement of future collective identities (Laitin, 1998). A third rational choice explanation holds that the collective identities associated with social movements – and, by implication, with other collectivities as well – can be regarded as 'selective incentives' for those who seek to express and affirm their personal identities (Friedman and McAdam, 1992). The explanatory utility of these arguments, as well as the network appropriation thesis, is contingent on two underlying assumptions: that there is preestablished congruence among some number of personal identities and the proffered or available collective identities; and that collective identities are constituted by the aggregation or convergence of parallel personal identities. While the first assumption is empirically tenable, the second is questionable from the vantage point of many scholars of collective identity (e.g., Jasper and Polletta, 2001; Melucci, 1989, 1995).

In the absence of correspondence between personal identities and collective identities, some variety of identity work is necessary in order to facilitate their alignment. This alignment can vary significantly, ranging from the elevation of the salience of a particular identity to a fairly dramatic change in one's sense of self. Four identity construction processes have been identified that capture this variation: identity amplification, identity consolidation, identity extension, and identity transformation (Snow and McAdam, 2000; see also Robnett, 2005). Identity amplification affects a change in an individual's identity salience hierarchy, such that an existing but lower-order identity becomes sufficiently salient to ensure engagement in collective action, as in the many cases in which in the identity of woman was elevated and expanded in conjunction with the Women's Movement; identity consolidation involves the adoption of an identity that is a blend of two prior but seemingly incompatible identities, as in the case of the union of environmentalists and labor activists and 'Jews for Jesus'; identity extension entails the expansion of the situational pervasiveness of an individual's personal identity so that its reach is congruent with the collectivity's, as when individuals come to see themselves as representatives for a specific cause that transcends other role obligations and identities; and identity transformation involves a dramatic change in identity, such that individuals now see themselves as remarkably different than before, as often occurs in the case of conversion to a new group or movement.

The mechanisms or processes underlying these various forms of identity construction include framing processes in which identities are announced or renounced, embraced or rejected, and modified or reframed in the course of various interactions with adherents, antagonists, and bystander audiences (Benford and Snow, 2000; Hunt et al., 1994); engagement in collective action, as when direct observation or experience functions as a demonstration event that gives rise to a situationally specific collective identity or affirms collective claims and thus helps to render salient, and perhaps pervasive, what was previously a secondary or marginal personal or social identity (Calhoun, 1991; Melucci, 1989); or some combination of both framing and actual engagement.

Given the variety of ways in which identity correspondence can be affected, the question arises as to whether the relevance of the convergence and construction processes varies by type of collectivity. In the case of social movements, for example, it has been hypothesized that movements that are culturally different, greedy in terms of the cognitive and behavioral demands, and/or politically radical are likely to rely more on identity construction than convergence processes (Snow and McAdam, 2000). Whether this is the case is an empirical question, but it does caution against presuming that what accounts for identity correspondence and shifts in one context necessarily holds for another. That context is clearly significant is highlighted in Reger's (2002) work analyzing different chapters of the National Organization for Women (NOW). She shows that the distinct cultural and geographical contexts of the local chapters affected the feminist identity constructed by women at each chapter. The relationship of context and identity construction is a fruitful avenue for future research.

Just as there may be variation between types of collectivities and the processes of identity convergence and identity construction, so it is reasonable to ask whether these processes might vary in importance at different points in the life course of a social movement or ethnic or nationalist mobilization? Rather than assuming that a particular process, such as the tipping process or identity amplification, operates routinely with respect to the emergence of a collective identity, might not these processes be more relevant at particular junctures in the career of a movement's collective identity? Preliminary consideration of such questions suggests that network appropriation, rational choice, and constructionist explanations, rather than being mutually exclusive and antithetical, may

interact and combine in interesting ways in explaining the emergence, institutionalization, and diffusion of collective identities across different contexts (Snow and McAdam, 2000).

Dimensions, Layers, and Types of Collective Identity

Although there is an extensive literature on collective identity, with considerable discussion regarding its conceptualization and sources, this literature has been relatively mute regarding variation in its form. The concept most often is invoked as if it is an invariant, uniform collective phenomenon. This is not the case, however, as collective identities can be multidimensional and multilayered within a specific locus, and they may also vary by type. The multidimensionality of collective identity is indicated by reference to its cognitive, emotional, and moral dimensions (Jasper and Polletta, 2001; Melucci, 1989). The relative importance of each of these dimensions to the vitality and motivational force of a collective identity has not been elaborated, however. Presumably, the presence of each of these dimensions yields a more robust and vital collective identity. Clearly a collective identity in which the boundaries between 'us' and 'them' are unambiguously drawn, in which there is strong feeling about those differences, and in which there is a sense of moral virtue associated with both the perceptions and feelings, should be a more potent collective identity than one in which either the emotional or moral dimensions are weakly developed.

Similarly, several analyses have noted that collective identity can be multilayered, such that there can be variation in its locus. Three such layers have been noted with respect to social movements (Gamson, 1991; Stoeker, 1995). They include, beginning with the broadest and potentially most inclusive layer: the social movement community or solidary group, which can be thought of as the constituent layer, as in the case of black Americans in relation to the civil rights movement; the social movement layer as in the case of the civil rights movement; and the organizational layer, as represented by the Southern Christian Leadership Conference (SCLC), the Congress for Racial Equality (CORE), and the Student Nonviolent Coordinating Committee (SNCC) in the context of the civil rights movement (alternatively divided as the 'activist,' 'organizational' and 'tactical' identity by Jasper (1997). In principle, each successive layer may be embedded in the larger more inclusive layer, giving rise to a generalized, cohesive collective identity at the community or national level. But clearly the existence of a collective identity at one level does not automatically generalize to or incorporate another level and each level of identity may exist alongside both movement identities and preexisting collective identities, interweaving with them in complex ways. Thus, collective identities can be built around the organizational carriers of a movement, as in the case of SCLC and SNCC, without necessarily representing the broader movement, which indicates the potential for identity conflicts at the collective level and the potential for schism and factionalization. Such observations suggest the need for more careful consideration of the often multilayered character of collective identities and of greater specification of the ways they can interact and combine, and with what consequences. As well, these observations call for caution in generalizing about the scope and functioning of collective identities, particularly with respect to broader social categories, such as ethnicities and nationalities.

Finally, it is reasonable to wonder if collective identities vary by type. At the most general level, Hunt et al. (1994) distinguish among protagonist, antagonist, and audience or bystander identities, arguing that even though protagonist or oppositional identities have received most of the scholarly attention, each type or field of identity is fundamental to understanding the interactive dynamics underlying the emergence, character, and functioning of a collective identities. Noting as well that collective identities arise and operate within an interactive context 'marked by power relationships,' Castells distinguishes among legitimizing, resistance, and project collective identities (1997: pp. 7–10). Legitimizing identities are associated with dominant institutions or the state, whereas both resistance and project identities represent two basic forms of the antagonist identity, the former generated by devalued and stigmatized collectivities, and thus constituting the seedbed for identity movements and politics, and the latter associated with movement beyond resistance to the construction not only of alternative identities but also a new system that valorizes rather than defiles the new identity. The important issue is not whether such typologies of collective identities are exhaustive, but the emphasis on their contextually embedded and interactional character and their different consequences.

Abstract

The rapid emergence of global memory archives presents a novel challenge for anthropological research. Media industries, commodity capitalism, and digital technologies have altered the practices and possibilities of collective remembering. Competing representations of the past are forged, deposited, and exchanged in virtual space. How do anthropologists investigate these modalities of social remembering and forgetting when the machinations of past experience and the formations of historical consciousness are increasingly uncoupled from local memory communities? Through a critical engagement with anthropological concepts, research agendas, and debates about the multiple linkages between remembrance, past experience, and history, this article attempts to uncover the impact of globalization on collective memory practices.

Focused on socially shared, collective memory practices, this article examines the linkages between memory and history with attention to the fields of power in which the struggle for domination over remembrance, retrievable historical consciousness, and collective forgetting takes place. Through a critical engagement with anthropological concepts, research agendas, and debates, the article uncovers the impact of globalization on memory practices. Media industries, commodity capitalism, and digital technologies have altered the possibilities of collective remembering. Uncoupled from memory communities, competing representations of the past are deposited and exchanged in virtual space. These fluid, expansive global memory archives pose a new challenge for anthropological research.

Definition of Concepts: Memory and History

The term *history* is often used to describe representations of the past that appear in written or narrative form, a primary medium through which states, elites, or dominant descent groups confiscate linear time and proclaim official chronologies as master narratives. The writing of history is a 'colonization' of time 'by the discourse of power' (de Certeau, 1988). The term *memory*, by contrast, is conventionally applied to those oral, visual, ritual, and bodily practices through which a community's collective remembrance of the past is produced or sustained (Connerton, 1989). It includes the vast complex of unofficial, noninstitutionalized knowledge not yet sedimented into formal traditions and which represent the 'collective consciousness' of whole groups (Halbwachs, 1980), forming a counterweight to the knowledge that is privatized and monopolized by certain elites for the defense of established interests. While memory may be a moving reservoir of history, furnishing the 'raw material' for representing the past, it is not the same as history (Le Goff, 1992). Individual remembrance, collective memory, and narrative history interact in highly complicated ways, shaping each other as different versions of the past are constructed and reconstructed, modified, and invented.

The Politics of Time: History and Anthropology

The theories, models, and methods developed by anthropologists to study non-European worlds tended toward a 'rejection of historical research of any kind' (Evans-Pritchard, 1962), at least within the limits of the discipline. Having as its central theme 'the unlettered and forgotten peoples,' the anthropological endeavor was inclined to disregard the existence of indigenous histories, which also included, in particular, the trauma of the colonial encounter. But if *making history* is a social practice that produces peoples, bodies, and places, as de Certeau (1988) suggests, then the very erasure of such a universe of time and being must be understood as a figuration of power. The effacement of historicity is a political operation.

Nineteenth-century anthropology was deeply implicated in the projects of Western modernity: the construction of nation-states and the creation of colonial systems with which Europeans came to dominate other worlds. During this process of global expansion and the establishment of modern hegemonic polities, the past was increasingly mobilized as a symbolic discourse 'in the definition of, and the marking of, the boundaries of states and nations' (Cohn, 1981, p. 228). Anthropologists of this period contributed to the colonial undertaking by a reliance on analytic tools that used Western notions of time as an index of unequal evolutionary development. The prerogative to know and control the past, by defining it as 'history' (an order of chronological or linear time), was an entitlement of civilization. The social worlds outside of Europe came to be marked as timeless: a closed symbolic universe inhabited by 'the people without history' (Wolf, 1982). Displaced into the sphere of alterity (Fabian, 1983), colonial subjects were incarcerated by the temporal logic of an expansive European world system.

The past as history became a way to construct schemes of classification that differentiated Europeans from others. Anthropologists began to delineate stages of human development via the comparative method: by identifying phenomena of a general type (taboo, totemism, polygamy), their goal was to map out a global history of social institutions. In this endeavor, however, analytic units were 'taken out of the flux of time' (Evans-Pritchard, 1962, p. 175): social forms, stripped of their unique features and context-bound meanings, escaped temporality, appearing static and unchanging. The comparative method, in its attempt to achieve conceptual stability as a sociological proposition, was explicitly antihistorical in

emphasis and thereby effectively obscured the effects of Western contact and domination.

By the early twentieth century, anthropologists had decisively abandoned the comparative paradigm. But in spite of the shift to new methods of analysis, the discipline's aversion to historical research intensified. Scholars in Britain, Germany, and the United States asserted that the customs of native peoples were to be found not in colonial archives, missionary reports, or dubious travel accounts but *in the field*: reliable data about non-Western societies demanded first-hand observation. This was accomplished at first through brief expeditions and later by long-term residence of the anthropologist in native communities. British scholars, in their interpretation of the ethnographic venture, reasserted the enlightenment program: anthropology was to become "a natural science of society, based on a descriptive analysis of the structure and functioning of social forms" (Cohn, 1981, p. 232). Later theorists deemed such a description of societal surfaces insufficient for a postcolonial anthropology of temporality. French critics like Claude Lévi-Strauss advocated for a humanist-philosophical approach that examined the deeper systemic framework whereby a people lived, signified, and imagined their own historical situatedness in cultural terms (Harkin, 2009). American scholars, by contrast, adopted a romantic idealist stance: in North America, anthropology emerged as a hermeneutic science, focused on the discursive reconstruction and symbolic capture of entire cultural systems. Although the nation-bound projects of anthropology began to diverge, the ethnographic field method was adopted as a common research standard, thereby imparting and codifying the now conventional disciplinary gaze: the observers' eyes were trained to *see* society only at a particular point in time. Ethnography, in its obsession with reifying the authenticity of native peoples, fabricated a closed temporal frame: a *present present* or a *past present*, as Evans-Pritchard (1962) termed it in a critical commentary on the discipline's 'breach with history', illuminating the distortions which flow from the imposition of a priori temporal limits upon indigenous societies.

But it was precisely this aversion to historical research that led anthropologists to discover 'memory' as a valuable ethnographic tool. Evans-Pritchard (1962), for instance, suggested that the past was always "encapsulated in a context of present thought": the past, as *memory*, was embedded in material, ritual, and narrative practices and therefore "part of the social life which the anthropologist can directly observe" (pp. 177–178). The pursuit of collective memory was to constitute a major change in ethnographic practice: the 'life story' of local worlds – of bodies, magic, and markets – could be rendered intelligible through the oral archive. But in the colonizing imagination of Western anthropologists, the work of memory was consigned to the uneventful register of *structural*, *mythical*, and *sacred* time: an order of signs without history. Peoples' means of remembering traumatic events (famine, migration, conquest) "were always seen to reinforce the system in place, never to transform it" (Comaroff and Comaroff, 1992, p. 21). In a shift from historical past to ethnographic present, anthropologists erected 'counterfeit signposts' of a primitive world of enduring traditions – an analytic fiction.

The anthropological fascination with 'unchanging' societies persisted. Signs of cultural duration, repetition, and reversibility were interpreted as evidence of timeless worlds that existed as antithetical counters to the West. Such assertions, following Mbembe (2001), postulated the possibility of temporal realities without historical agency: social life purportedly proceeded 'by the blind force of custom,' moved by 'charms, spells, and prodigies,' and "time [was] supposedly stationary," governed by "the importance of repetition and cycles, and the alleged central place of witchcraft and divination procedures," thereby defining a social landscape inhabited by people who were "caught in a relation of pure immediacy to the world and to themselves," living life as 'libidinal machines' (pp. 4, 15). Such notions endorsed the authority of European world-domination by claiming empirical objectivity. In turn, the colonial gaze attached sociotemporal otherness to a visual frame, 'an aesthetic of respect for the status quo' (Fanon, 1994, p. 3). Anthropological subjects were thus apprehended in terms of a 'complex of visuality,' as Mirzoeff (2011) elaborates, which incarcerated temporal difference in an 'aesthetics of the proper,' perceived as 'pleasing, ultimately even beautiful' (pp. 3–4). While the abrogation of indigenous histories and temporal experiences was transformed into an aestheticized artifact by colonial intervention, creating the figure of the 'ritualistic, tradition-bound native,' critical anthropological inquiry into postcolonial pasts was censured by an affective charge: 'hostility,' 'revulsion,' and, at best, 'inattention'(Evans-Pritchard, 1962, pp. 172–191). The anthropology of collective memory, in consequence, began as a kind of antihistory.

The Shape of Memory: Modes of Historical Consciousness

In their ethnographic explorations, anthropologists encountered indigenous memory forms that did not seem to fit the European idea of historical time: an objective, unmediated, linear account of past events. Divergent temporalities were interpreted as premodern forms of consciousness, modeled on the periodicity of nature: seasonal changes, plant fertilities, female rhythms, and lunar cycles. These assertions have since been contested (Munn, 1992). A reevaluation of the ethnographic evidence suggests that indigenous memory practices do not negate time by simulating nature. Rather, historical experiences are often spatially encoded: memory archives are attached to landscapes to recall place-specific events or the movement of people, bodies, and objects across a topographic terrain (Greenhouse, 1996, pp. 39–48). This mode of time keeping is not nature based. The morphologies of space are meaningfully mapped to record political, economic, or social events. Oral histories and collective memories can thus be archived and retrieved by reference to spatial markers. Ironically, by naturalizing non-European constructions of historical time, anthropologists began to scrutinize the symbolic fabric of society for signs and indexes of such mimetic practices. These investigations led to unforeseen discoveries.

By a focus on myths, ritual, oratory, and body practices, anthropologists uncovered the narrative and performative possibilities of *a history of the present*: the social sense of time whereby people attempted "to grasp the world as both a synchronic and a diachronic totality" (Lévi-Strauss, 1966, p. 263). In the realms of memory, past and present – although

theoretically distinct – were conjoined to link, from generation to generation, the living with the dead. Among Australian aborigines, for instance, *historical* or *commemorative rites* "recreate the sacred and beneficial atmosphere of mythical times—the "dream age"—mirroring its protagonists and their great deeds," and transport "the past into the present"; *rites of mourning* 'correspond to an inverse procedure: instead of charging living men with the personification of remote ancestors, these rites assure the conversion of men who are no longer living into ancestors,' thereby bringing "the present into the past" (Lévi-Strauss, 1966, pp. 236–237).

These images of time are different, perhaps, but not 'other.' In the rites performed, past and present are propelled into a social space – the body. The act of remembering takes corporeal form: memory is embodied (Connerton, 1989). When inhabited or possessed by the past, performative bodies articulate "the means by which a narrated ancestral event is given 'presence'" (Munn, 1992, p. 113). But this transposition of temporal worlds, which connects the living and dead to the ancestors via the mimetic power of embodiment, is not an abrogation of time. It is a generative reconstitution of society: a practice of empowerment, a political engagement with the matrix of life (Stoller, 1995). This attentiveness to indigenous body-time paradigms galvanized memory research in Europe, thereby closing the postulated rift between 'Western' and 'non-Western' approaches to temporal meaning (see Badone, 1989; Herzfeld, 1991; Kertzer, 1989; Kligman, 1990; Verdery, 1999). In all societies, representations of the past are forged by the synergies of symbolic processes and the contingencies of life.

Anthropological studies further suggest that collective memory may be systematized on the basis of *relative temporalities*, that is, a flexible system of polymorphous reference points. Among certain peoples of the Ivory Coast, like the Guéré, "the consciousness of a historical past has developed alongside a multiplicity of other times" (Le Goff, 1992, pp. 8–9): *mythical*, *genealogical*, *historical*, *lived*, and *projected time*. Such a register of memory forms belongs to the aftermath of the colonial project. This observation is congruent with the historical reverberations of struggle 'in the postcolony,' as Mbembe (2001) asserts, where the 'languages of life' always consist of 'a combination of several temporalities' – brought into being by *memories of living* in the concrete world and the entanglement of *existence and experience* in times of 'instability and crisis' (pp. 15–17). Under the impact of prolonged social trauma, the disparate logics of time and memory chart the precarious matrices of life: a synchrony of struggle, violence, and perseverance. In the 'afterlife of collectively experienced catastrophes,' these knowledge of the past can be deployed as a 'political language' to affect future change (Radstone and Schwarz, 2010, p. 3). By the twenty-first century, anthropologists shifted their investigative focus, turning attention from ethnographic inventories of polymorphous memory archives to the politicization of historical consciousness.

Memory sites: The Localization of Remembrance

The anthropological analysis of collective memory moves toward a renunciation of linear temporality in favor of multiple kinds of time as experienced at the levels where the individual takes root in the social: language, demography, kinship, economics, and politics. Memory production is in this sense not dependent on a single individual's experience of the past. A remembrance, a social understanding of events that is represented as memory, can be constructed by sharing with others "sets of images that have been passed down to them through the *media of memory*—through paintings, architecture, monuments, ritual, storytelling, poetry, music, photos, and film" (Watson, 1994, p. 8). In every society, we can identify an array of memory sites or places of commemorative record and practice where remembrance anchors the past: *topographical* places (archives, libraries, museums); *monumental* places (cemeteries, architectural edifices); *symbolic* places (commemorative rites, pilgrimages, emblems); *functional* places (manuals, autobiographies, associations); and places of *power* (states, elites, milieux) which "constitute their historical archives in relation to the different uses they make of memory" (Le Goff, 1992, pp. 95–96, Nora, 1986). These memory sites furnish a series of locations where knowledge of the past are conveyed and sustained by a circulation of signs that focuses meaning on pertinent ideas, values, and feelings.

In this era of globality, the relation of collective memory to locality and place has been reframed. Conventional sites of remembrance are replaced by virtual images. Digitalized knowledge of the past travel across national borders and communal solidarities. New information technologies provide historical imaginaries with alternate vectors of space–time orientation. In her work on the contested state in Cyprus, Navaro-Yashin (2002) tracks the political implications of such altered memory capacities. Her research shows not only how local histories are complicated by military violence, law enforcement practices, and international legal discourse, but also the limitations of subjecthood imposed by regimes of 'documented lives.' State-issued documents such as passports, birth certificates, visas, identity cards, and work permits are sites of political memory and indexes of state power, which capture and reveal life histories. While these portable docu-memories of the state may be authenticated in police archives or judicial record rooms, enhanced identity profiles are stored in electronic space – together with biometric scans, fingerprints, and criminal histories. Digital technologies can transmit a state's 'memory of a people' across the globe, permitting instant and total recall of archived data – from citizenship portfolios to security profiles (Matsuda, 1996, p. 121). Located in the virtual realms of electronic space, the political memory banks of belonging and exclusion have become transterritorial and transglobal.

In a globalizing world, the anthropology of collective memory acquires a new vantage point. Entrenched inequalities are evident across continents. Local experiences are identifiable as worldwide patterns. Postcolonial and posttotalitarian strands of historical consciousness can be globally mapped, permitting an analysis of cognate memory traces from different existential life-worlds of the *Global South*: an imagined territory and a relational space that has been configured "by its structural and tropic situation in the history of the ongoing global present" (Comaroff and Comaroff, 2012). From this perspective, collective memory practices must be understood

as situated political formations. Across the spaces of the global south, postindependence representations of colonial pasts may become oppositional, liberatory, or revolutionary. In each case, the multiple registers of temporality and historical experience serve as a weapon of choice against the mythologies of premodernity (*Orient, Third World, Primitive Other*) that were so violently propagated by the empires of the world's north (Comaroff and Comaroff, 2011). A global vantage point also sheds new light on the creation of 'affective communities' across political spaces, as Casey (2009) shows in her analysis of citizenship, Hausa Muslims, and violence in northern Nigeria: media flows shape translocal solidarities by infusing alternate registers of history and truth with composite memories of identity, affect, and belonging.

Unsanctioned Archives: Memory and Countermemory

The anthropology of collective remembrance is not only concerned with affirmation and heritage, but with processes of contestation, the aftermath of violence, and the emergence of countermemories (Stoller, 1995). *A social history of remembering* must take account of 'the mechanisms that make unsanctioned remembrance possible' under repressive political regimes: in asking how people remember what is meant to be forgotten, 'matters of transmission' and the procedures for creating shared memories and hidden histories take center stage (Watson, 1994). Here, interpersonal memories, commemorations, theater, drama, folklore, secret, and oppositional histories are 'the venues within which alternative remembrances' – unauthorized and unapproved memories of the past – can be located and analyzed (Watson, 1994, p. 2). Collective memory practices are linked not only to sites of domination that attempt to legitimate a given social order, but also to unsanctioned sites of struggle, opposition, and transformation.

In attempts to decipher the underground historical consciousness of ordinary people, anthropologists began to investigate the unarticulated truths or 'hidden transcripts' (Scott, 1990) that emerged communities stripped of agency and power by a centralized state apparatus. Initial research on these hidden collective memory forms or 'public secrets' (Taussig, 1999) in Latin America, the Soviet Union, and Eastern Europe triggered further interest in 'perilous' or dangerous memories that had been forged in contexts of war – the silenced remembrances of suffering that posed a challenge to official histories: examples include local memories staged against the allied liberation narratives propagated in the Asia-Pacific Wars (Fujitani et al., 2001) or memories of 'evasive spaces' in the domestic interior of Dutch colonialism in Southeast Asia (Stoller and Strassler, 2000). With attention to the possibilities of 'effacing' dominant screen memories (Taussig, 1999), anthropologists began to examine the stratigraphies of remembered truths in the aftermath of genocide and militarism (Feldman, 1997; Hinton, 2005; Linke, 1999; Robben, 2005). Such studies point to the complexities of societal recovery after the trauma of mass violence or colonial terror. "At issue is the political life of imperial debris, the longevity of structures of dominance, and the uneven pace with which people can extricate themselves from the colonial [or political] order of things" (Stoler, 2008, p. 193). Countermemory studies analyze the impact of unsanctioned archives on the emergent sense of transnational justice in posttrauma contexts.

The Traffic in Memory: Global Hegemonies and Local Struggle

In all societies, there exist distinct moments when alternative representations of the past are forged, contested, and used for new cultural or ideological projects. Battles waged over ethnic origin or national identity may be linked to the constitution of radically new kinds of memory archives (Hobsbawm and Ranger, 1983). The creation of nations, ethnicities, and subjects inevitably alters the shape of the past. "Memory" is therefore "not a generic term of analysis, but itself an object appropriated, transformed, and politicized" (Matsuda, 1996, p. 6). Or, put differently, memory can be nationalized, aestheticized, and commodified, offered up for purchase or branded for consumer attention.

Historical consciousness shaped by nation-building, scientific discourse, and global capitalism plays a significant role in the formation of social identities. Detailing the politics of remembrance in postsocialist China, Schein (2000) shows how state-orchestrated reforms, staged against the chaos of the Cultural Revolution and implemented during a period of increasing exchange and fascination with the west, produced a popular appetite for exotic others: commodified images of minority peoples, like the Miao, were fashioned by an acute nostalgia for 'ancient' traditions and those feminized cultural essences on which to recraft a distinctive Chinese nationness. The result was a boom in memory recuperation among China's urbanites and Miao elites, who simultaneously played to a Western valorization and high-spending tourist consumption of dwindling pasts. But such a newly forged cultural attachment to memory artifacts, the 'fossil bed' phantasms of folk heritage, also entails transformation. In other words, the work of symbolic restoration 'may conceal very new projects' (Le Goff, 1992, p. 9). The recruitment of the past for revolutionary or political ends, as in the case of China, is entangled in a twofold venture: the forging of a distinctive ethnonational imaginary and the renegotiation or recalibration of *place* in the global order.

The pursuit, rescue, and celebration of collective memory is always socially motivated and has, thus, to be understood in positional terms. The global context – the theater of transnational consumer capitalism – is, according to Friedman (1994), particularly relevant in understanding how local memory forms are affected by the formative impact of world systemic processes. In the case of modern Greece, as Friedman shows, national selfhood was crafted by internalizing the ways in which European elites, in constructing their own 'civilized' origins, mythologized classical antiquity as the cradle of Western civilization. Greek nationalists found their past in the institutional memory of the West, thereby accelerating incorporation into an expanding European world system. Such acts of cosmological repositioning are symptomatic of a transglobal system that fuses socioeconomic transformation and collective

memory to "the reconfiguration of the map of the world's peoples" (Friedman, 1994, p. 123).

Yet even in the global arena, there exist other possibilities of memory production. In the Hawaiian case, Friedman's instructive contrast, indigenous communities attempted to extricate themselves from Western dominance by projecting a value system, produced in the modern context, onto an aboriginal past. The result was a body of memories composed of mythic history, a work of folklore and folklorization 'rife with simulacra of tropical fantasies.' Social and economic marginalization, in the aftermath of World War II, gave rise to an intense period of Hawaiian cultural revival. Recuperation efforts, centered on the reconstitution of ethnic history by retrieving precolonial social forms, brought into play a *museology of memory* that was staged in opposition to the West: a precontact Hawaii stocked with all the items to be found in Western historical archives – libraries, museums, and missionary records. The Hawaiian confiscation of these colonial memory stores proceeded, as Friedman documents, by forging an indigenous past uncoupled from the larger world, a Western-imposed modernity, which had obliterated a population and absorbed its social history into the projects of global economic systems.

Anthropologists have firmly established the need to attend to these paradoxes of mobile cultural and symbolic forms – this *traffic in memory* – during periods of transnational crisis and restructuring (Appadurai, 1996). In the context of global systems, where the practice of identity is brought on stage, the logic of time and the meaning of memory have been radically transposed.

Global Memory Markets: Commodifying History, Commercializing Violence

In the global arena, the production of historical consciousness becomes increasingly entangled with the commodity form: encoded by temporal longings and mythic value, it furnishes the common stock for a *memory market* saturated by cargo-type products of surplus and lack, bearing the deep imprint of the globally hegemonic mode in which people's ethnonational remembrances are manufactured, exchanged, and consumed (Taussig, 1980). Inserted into the media circuits of commodity capitalism, historical consciousness is rendered portable. "The global reach of Hollywood allows certain images of the past to be exported around the world" (Morris-Suzuki, 2005, p. 243). But such memory forms are not transported innocently. Representations of the past have become commodity objects, made for profit. In the contemporary spaces of cultural production, photography, comic books, performative theater, the museum, entertainment industries, and cyberspace serve as conduits for nourishing the consumptive appetites of global publics. Select trauma histories circulate as universal tropes for other human atrocities. The Holocaust is an exemplary case. By exposing the linkages between modernity, racialization, and violence, as Hyussen (2003) argues, Europe's genocide has acquired a totalizing dimension that is continuously appropriated and meaningfully attached to other "local situations that are historically distant and politically distinct from the original event" (pp. 13–14). Such emergent memory markets do not necessarily inhibit critical inquiry but may pose "fundamental questions about human rights violations, justice, and collective responsibility" (p. 15). Nevertheless, the mass-mediated traffic of *present pasts* encourages a habitus of selective remembering, rendering some aspects of traumatic events hypervisible while muting the recall of others.

In a consumption-driven capitalist world, memory industries obliterate temporal boundaries and destabilize the precarious relation between remembering and forgetting. Mass-mediated productions of historical events flourish on narrative plots scripted by corporate interest. Representations of the past are fabricated, staged for popular entertainment. Such a collage of fiction and memory, unlike remembrances produced by collective experience or lived time, is not 'embodied in the social' and therefore more easily forgotten: commodified memory "is sucked into the timeless present of the all-pervasive virtual space of consumer culture" (Hyussen, 2003, pp. 10, 28). These transient, fleeting 'memories of the modern' (Matsuda, 1996) tend to destabilize a secure sense of the past. Guided by market principles, mediated historical consciousness is a product of 'prosthesis' memories (Nora, 1989, p. 14): a repertoire of simulated temporalities, composed of recycled image fragments and fictional texts that conjure an affective engagement with the past via shock-effect or mass-produced sentiments of nostalgia and commemoration. As 'prosthetic' implants, such consumable memory artifacts have the "capacity to create shared social frameworks for people who inhabit different social spaces, practices, and beliefs" (Landsberg, 2004, p. 8). In a global media market, translocal identities and transnational solidarities are forged by consumer-directed memory productions that mimic a sensuous engagement with imagined historical realities (Neiger et al., 2011). Stocked with prosthetic memories and consumable pasts, global commodity culture is increasingly marked by fears of forgetting the phantasmatic and surreal.

What sorts of memory markets have emerged to counter these popular anxieties about the slippage of temporal experience? Through the interventions of commercial media, trauma history has come to the attention of a bourgeoning tourist industry. Commercial sightseeing tours and venture capitalism flourish in areas of former violence, suffering, and mass destruction: examples include the battlefields of Europe, sites of genocide at Auschwitz-Birkenau, the Killing Fields of Cambodia, and the ruins of New York's Ground Zero. These are the negative spaces of history: the nonvirtual, archaeological sites of a bygone world or past event defined as inhumane, catastrophic. This memory genre belongs to a broader pattern of commodity consumption variously described as 'dark tourism,' 'disaster tourism,' and 'trauma tourism' (Lennon and Foley, 2000; Stone, 2006; Stone and Sharpley, 2008; Gotham, 2007). Such practices are focused on sites of human tragedy that can be branded, showcased, and meaningfully reimagined by consumer travelers. Organized venture tours not only promise to deliver memorable experiences: by touring sites of past violence, memory is socially constructed, from 'lived' life (however episodic), which is authenticated by the event's sightseeing experience shared by tourist participants. Through the ready-made vignettes of space and time, as Sturken (2007) has argued, trauma tourism markets

'comfort culture': it propagates fear to sell safety; it offers prepackaged emotions to replace traumatic memory formations with kitsch sentiments for purchase. Collective memory practices are thereby arrested in time, permitting a constant replay or reenactment of history with the promise of return to a secure present that is "somehow distanced and unimplicated in the global strife of the world" (Sturken, 2007, pp. 3–4). Violence remembered remains in the past, as an artifact of a distant time, a different temporality. Trauma tourists participate in a shared experience, consuming prosthetic memories as ready-made versions of history. The social construction of collective memory is thereby simulated by time-travel into the contact zones of the past: touristic encounters with history are mediated by the hegemonic representations of commodity realism.

In the global marketplace, memory consumption can also be a subordinate production, one that creatively and tactically resists the homogenizing tendency of centralized regimes. With a focus on the political economy of memory culture in Latin America, Bilbija and Payne (2011) scrutinize the posttrauma labor of remembrance in Argentina, Brazil, Chile, Mexico, Peru, and Uruguay, in countries where traces of repressive political regimes continue to reverberate in everyday life. The commercial use of memory artifacts (e.g., testimonials, places of terror, prisons, paraphernalia) transports accounts of past atrocities and state terror into the public domain. Such publicity can inspire alternative engagements with existing memory stores or turn attention to human rights agendas. But not all commercial memory projects advocate for justice. The commercial recall of past violence promotes consumer culture. This is suggested by the conversion of a former prison complex into a shopping center, the staging of state terror as a backdrop for the love-triangle plots in Brazilian (Globo) television novellas, or the use of atrocity images in corporate ads for jeans in Argentina or Chile that 'render torture sexy and trendy' (Bilbija and Payne, 2011, p. 24). Although past violence is commodified, capitalist memory markets acquire political momentum when cross-coded with transglobal ideas of justice or human right agendas captured from beyond the borders of the nation-state. Inflected with political meaning, and reinterpreted as an ontological discourse of visibility, the presence of historically charged trauma images in the public sphere 'defaces' official screen memories, thereby lifting the veil of secrecy and silence placed upon an unutterable, muted past (Taussig, 1999). By contesting the state's authority of censorship, collective memory sharing in the marketplace is thereby equated with 'the right to look' (Mirzoeff, 2011), even though this demand for freedom and truth is mediated by the logic of commercial culture. Commodity practices not only render muted histories perceptible. As past violence is made consumable, it becomes memorable. What is collectively remembered about past terror may be dictated by capitalist intervention. Nevertheless, the 'politics of interpretive license' (Stoler and Strassler, 2000, p. 5) introduce unconventional tactics of meaning making and signification, and as such remembering. This suggests, as Schein (2000) observed, an alternate sense for collective memory production: "the myriad ways in which people make use of received cultural products presents a measure of possibility, not only for autonomy, but also for subversion of the dominant order" (p. 16). Put differently, the modalities of collective memory practice attest to the possibilities of *symbolic creativity* – even in the province of globalizing modernities or consumer capitalism.

Memory of the World: Globalizing Collective Remembrance

How are collective memories constituted in a global world? Under globalization, the 'spaces of memory and the composition of memory communities' have been reconfigured (Assmann and Conrad, 2010, p. 1): not only are memories themselves rendered portable but events may be simultaneously witnessed in real time by differently constituted publics. While representations of the past continue to be framed by national agendas, transglobal memory archives are stocked with data snippets pooled from socially unrelated subjects worldwide. Memory is no longer a stable repository of the residual traces of shared life experience. The planetary proliferation of electronic media has altered the possibilities of memory recall and input across the globe: moments in time can be recorded, stored, then 'brought back to life, restaged, or replayed' (Winter, 2012, p. 4). Individualized access to the Internet has changed practices of remembering. Digital forms of communication (email, Facebook, Twitter, YouTube, Skype, blogging) offer new venues for memory sharing beyond conventional boundaries of nation, culture, and community. Transported through cyberspace, bits of 'digital network memory' (Hoskins, 2009) reside in virtual timescapes, where temporal records can be speeded up or brought to a standstill, creating parallel universes of memory, time, and space.

In the "wake of the information explosion and the marketing of memory" (Hyussen, 2003, p. 18), the societal dialogue with lived historical experience has been disrupted. Global memory stores are expansive, gaining momentum through new forms of representation, memorializing, knowledge recycling, instant recall and replay of temporal experiences, data simulation, copying, and replication. Although "memory has become a cultural obsession of monumental proportions across the globe" (Hyussen, 2003, p. 16), it is driven by consumer culture and corporate desire rather than the existential machinations of ethnosocial communities. Global media industries favor 'random access memories' and episodic attention to news worthy events (Morris-Suzuki, 2005). Competing versions of past experience rise to the surface of data-saturated awareness by the media hype of spectacle, advertisement, and entertainment. The formation of global memory markets productively engages postmodern instabilities: a world of shifting imaginaries, inhabited by flows, fragmentation, and forgetting. The eventual shrinkage of collective memory in the global theater poses a challenge for conventional anthropological research. What happens to the discipline's humanistic endeavor in light of this emergent 'future history of the world' (Lévi-Strauss, 1952, p. 49)? Twenty-first century anthropology needs to grapple with the implications of fluid temporalities and shifting memory imprints in a virtual world of global culture politics.

Abstract

Collective memory has been the subject of productive interactions within the social sciences ever since its initial conceptualization. Employing a social interactionist framework in which large-scale phenomena are empirically investigated as interactions between cognition and social dynamics, the article presents psychology's contribution to understanding the formation and the dynamics of collective memories.

Collective memory has had a long history within the social sciences. It served, in the period since Halbwachs's landmark conceptualization (1980/1925), as a meeting place for interdisciplinary conversations involving sociology, history, anthropology, and psychology (Hirst and Manier, 2008). As any constructive dialog, conceptualizing collective memory has been ridden with theoretical disputes ever since the emergence of the concept. Methodological individualism, an approach aimed at deterministically deriving collective phenomena from the psychological make up of individuals and their interactions, constituted the main issue of contention (Udéhn, 2002). Although, it is beyond the scope of this article to provide a review of methodological individualism and its nuances, the burgeoning literature on the psychology of collective memory provides substantial evidence that bridging between micro and macroprocesses is a worthy endeavor (DiMaggio, 1997). In what follows, I will briefly present approaches within the social sciences that allow for a psychological exploration of collective memory, I will then articulate the psychological assumptions of such an endeavor, and finally, I will review the burgeoning psychology literature aimed at bridging between micro and macroprocesses.

Collective Memory: A Case for Its Psychological Foundations

It is widely accepted that just as individuals have memories of their own personal pasts, so do collectivities have memories of the events that are central to their identity. What is contentious, though, is whether to understand these collective memories, one needs to take into account how individuals remember, or simply restrict oneself to the study of the social processes involved in their formation. Widely credited with the articulation of the concept, Maurice Halbwachs was mindful of the fact that individual memory is critical to understanding collective memory. "It is individuals as group members who remember," he claims (Halbwachs, 1980: 46). The critical notion that individuals remember as group members stands at the crux of his conceptualization of memory as inherently social: from the very basic usage of a particular group's language to reminisce to the social dimension that accompanies the act of communicating a memory. Given the belief that it is impossible to separate what is individual and what is social about memory, he cautions against looking into the brain or in some 'nook of (the) mind' to understand memory, for memories "are recalled by me externally, and the groups of which I am part at any given time give me the means to reconstruct them" (Halbwachs, 1980: 46). It is in light of this unbreakable link between the individual and its social embeddedness that Halbwachs proposes the study of the social frameworks in which memory is manifested.

This ambiguity of locating collective memory in either individual minds or in the social processes that govern their creation has received extensive attention among social scientists. In contrast with Halbwachs's acceptance of the ambiguity, most current approaches seek to resolve it by clearly differentiating between endeavors that commit to one location or the other. Young (1993), for instance, differentiates between 'collected memories,' defined as the aggregation of individually produced social memories, and 'collective memory,' seen as collectivistic cultural activities or productions (see Olick, 1999; for a similar distinction). In final analysis, he argues, "societies cannot remember in any other way than through their constituents' memories" (1993: xi). In a similar attempt to provide clarity to the concept of collective memory, Jan Assmann distinguishes between communicative and cultural memories. The former are conceptualized as conversationally constructed memories that have limited time horizons, the latter are seen as long lasting, publicly available cultural products (e.g., monuments, texts, images, rituals) designed to emphasize meaningful events in the history of the group. It is only in those instances in which communicative memories get transformed into 'objectivized culture' that they become cultural memories (Assmann, 1995: 130). Individuals and their interactions are, according to Assmann, critical only when considering transient communicative memories. The focus of collective memory scholars should be, he claims, the stable cultural memories and the struggles behind their enactment.

What emerges in the social sciences is, then, a dichotomy as to whether understanding collective memories requires the integration of memory processes that are specific to individual memory (Olick, 1999). On the one hand, there are efforts to carve out the 'spaces' where individuals are critical units when discussing collective memory, in concepts such as collected memories and communicative memories. On the other hand, approaches that follow an antiindividualistic

stance (Assman, 1995; Connerton, 1989) advocate that the study of collective memory be completely divorced from its anchoring within individual minds. To resolve this antagonistic dichotomy, Olick suggests a framework, under the heading of 'social memory studies,' that would allow disciplines to carry out their independent research programs in a way that respects their theoretical and methodological differences. Collected memory scholars would study the aggregation of memories, whereas collective memory scholars would carry out investigations of institutionalized objects.

A social interactionist approach stands in contrast to these dichotomous perspectives. It accepts that one cannot easily separate, as Halbwachs contended, the individual from the social. Social processes are constituted by individuals' interactions, and so they are dependent on individual characteristics, whereas individual behavior is dramatically affected by the social contexts in which it is manifested. Integrating this interdependence, a social interactionist position insists that one cannot understand how social artifacts and practices affect memory without considering individual cognition (Hirst and Echterhoff, 2012). This approach builds on recent philosophical developments in the theory of mind, specifically, work on extended mind and distributed cognition (Clark and Chalmers, 1998; Michaelian and Sutton, 2013). According to this view, the mind is part of a larger system that incorporates the environment, including the social contexts in which individuals function. To understand the navigation of a ship, for instance, one has to understand the complex system that produces the act of navigation. A system that includes the interdependence of individuals who are responsible for the navigation, the communication system that coordinates the interdependent individuals, and the equipment that allows for the integration and calibration of the different components (Hutchins, 1995).

In this context, psychology has set out to investigate how a perspective that takes into account both individual cognition and social dynamics could contribute to understanding the formation and the dynamics of collective memories. In what follows, I will trace the history of this social interactionist approach, explore how it leads to an empirically based investigation of collective memory, and finally present the recent empirical advances in the field.

Social Dimensions of Memory

Ever since psychology embraced the experimental method to study the mind, the individual has been, for the most part, the exclusive focus of its investigations. Given this focus, a topic such as the formation and dynamics of collective memories seems to be orthogonal to both theoretical and methodological advances within psychology, particularly with recent developments in neuroscience (Mather et al., 2013). Despite the prevailing individual reductionism, the social nature of memory has been a topic of rigorous psychological research from the early days of experimental psychology. In an extreme form of individual reductionism, one of the first experimental psychologists to explore memory, Herman Ebbinghaus (1913), carefully designed his stimulus material to strip away its contextual and social dimensions. He used nonsense syllables and took precautions to make these syllables as distinct from natural language as possible. The reasoning was that any associations that these syllables might trigger would interfere with one's ability to understand how memory works.

Stripping these dimensions away, Sir Frederic Barlett (1932) claimed, left nothing to be studied. Taking a perspective consistent with Halbwachs's notion that memory is inherently social, Bartlett embarked on programmatically studying the social dimensions of memory. For Bartlett, memory was akin to a tennis stroke. Just as when serving a ball, different contextual factors, such as wind speed, position of the sun, and the location of the opponent, will affect one's serve, so is remembering influenced by the context in which it is manifested. No two strokes, even by the same individual, will be exactly the same because of the variations in the different contextual factors. It follows that no two acts of remembering, even of the same memory by the same individual, will be exactly the same. In this conception, memory is less of a reproductive replica of the past, and more of a reconstructive process affected by a host of contextual factors. Consistent with this realization, Bartlett introduces the concept of *schemata*, which he defines as organized structures of knowledge that act as scaffolds for remembering. It is through these schemata, he argues, that the profoundly social nature of memory becomes manifest. They are acquired and fine-tuned within the groups that one belongs to, and they constitute the generative engines of remembering (Bartlett, 1932). The cultural schemata we develop during socialization processes, Bartlett argues, not only guide what we pay attention to, but also circumscribe how and what we remember (Wertsch, 2002).

Collective Memory from a Psychological Perspective

Building on the idea that memories are socially constructed (Bartlett, 1932), and emboldened by a wider acceptance of an extended mind philosophical tradition (Clark and Chalmers, 1998), psychologists have recently made collective memory a matter of not just sociological, but psychological concern (Hirst and Echterhoff, 2012). The framework that allows for these advances is one in which collective memories are defined as shared individual memories that bear on people's identities (Coman et al., 2009; Hirst and Echterhoff, 2012). By conceptualizing collective memories as shared individual memories, psychologists have committed themselves to answering several questions. First, how do memories become shared, and what are the psychological mechanisms that account for their sharedness? This set of questions falls under investigations of the process of the formation of collective memories. A second set of questions has to do with the form that these shared representations take. The focus here is not on the processes that underlie remembering, but on the outcome of these processes at a collective level. Psychology has made significant progress in answering these questions, but before we delve into it, I will briefly articulate the psychological assumptions that allow for a programmatic investigation of the psychology of collective memory.

Psychological Assumptions

I have thus far argued that individual cognition and social dynamics interactively shape collective memories. In this section, I will discuss three claims that have received extensive support within psychology and are fundamental to understanding the emergence of shared representations of the past:

1. Memory is reconstructive. As evidenced in the tennis strike metaphor (Bartlett, 1932), remembering is seen as a flexible reconstruction of the past, in which the audience, future goals, and the context in which it happens, are all critical factors that determine what form memory would have (Schacter, 1999).
2. Individuals conform. When placed in a social context, individual behavior is drastically affected by the constraints of such a context. Individuals' memories are, for example, affected by suggestions or recalls offered by others in a social group (Hirst and Echterhoff, 2012). And the reconstructive nature of memory is what allows for these suggestions to become completely internalized and remembered as valid representations of the past, even though individuals never experienced them (Edelson et al., 2011).
3. Individuals identify with groups. Extensive research within social psychology has explored the processes involved in group identification, but also the implications that such identification entails. Favoring the in-group and derogating the out-group, preferential attention to group-relevant information, and the motivation to construct a common ground with fellow group members represent biases that favor the emergence of collective memories (Ellemers et al., 2002).

It is the combination among memory's flexibility, and the individuals' tendencies to conform to and identify with groups that give force to an approach aimed at understanding the formation of collective memories. What results from the integration of these psychologically grounded claims is a social interactionist approach that takes into account both the individual cognitive mechanisms, such as memory's flexibility, but also the social dynamics surrounding people's interactions, such as the specific ways in which they influence one other. In focusing on memories growing out of human interactions, the social interactionist approach sees remembering as embedded in social activities. Conversations, as such central social activities, provide a fertile ground for psychological investigations of collective memories (Hirst and Echterhoff, 2012).

Collective Memory as a Process: A Social Interactionist Approach

Shared representations are created through complex processes. While recognizing the intricate linkage between the cognitive and social dimensions governing their formation, researchers have recently taken on the challenge of studying these processes empirically. In this section, I will first describe work on shared attention that allows for the emergence of shared representations in the absence of communication, I will then turn to the larger literature on the impact of conversations on memory in dyads and small groups, and I will end the section with recent work aimed at understanding how shared representations emerge in social networks.

Noncommunicative Processes

Most of the process accounts of collective memory emphasize the conversational nature of their emergence. Bartlett's notion of schema is, however, consistent with the idea that shared representations of a particular event could emerge even in the absence of social interactions. By using similar schemas to filter incoming information, individuals can form similar representations of the past. These schemata are, of course, acquired by way of interactions among individuals, but once they are part of a person's repertoire, they will automatically guide the encoding and retrieval of information. Group membership and situation typicality increase the chances that independent individuals use similar schemas to make sense of an event (Mandler, 1984).

Shared Attention Mechanisms. Recent investigations show that shared representations of the past could emerge in the absence of communication. Individuals, it was found, pay preferential attention to, and better remember, information that they believe similar others have access to at the same time (Shteynberg, 2010). In this particular instance, this shared attention mechanism makes people focus on the presented information unselectively, just by virtue of it being attended by similar others. This increase in shared attention could also guide participants as to what specifically to attend to. The resultant selective attention could create similar representations of an event, as when one is exposed to media coverage of causes of group-relevant conflict, for instance, simply because group members use their shared heuristics to decide what is salient for one's own group (Hastorf and Cantrill, 1954; Vallone et al., 1985).

Communicative Processes

Most typically, however, researchers have focused on the way people influence one another in a more direct fashion. An extant literature has focused, for instance, on how communicating about past events influences people's memories and renders them more similar.

Audience Tuning/Shared Attention. When we communicate to an audience, be it another person or a large group, we often have expectations as to what the audience wants to hear. These expectations affect not only what one communicates to others, but also the communicator's subsequent memories. Speakers, for example, often recount stories of the past in a biased manner to fit the audience's expectations. Interestingly, though, this effort to align one's message to the audience's expectations only results in altered memories consistent with the communicated message in situations when the speaker is motivated to create a connection with the audience. That is, only when speakers are motivated to share their beliefs, values, and attitudes with their fellow interactants does audience tuning result in consistent memory changes (Echterhoff et al., 2008). These motivations to create a shared reality can facilitate, thus, convergent memories between speakers and listeners.

Conversational/Dyadic Interactions. Most of our interactions are, however, in the form of extensive conversations in which content is exchanged bidirectionally. There is extensive

empirical research on how these conversations affect our memories. In these conversational paradigms, participants are instructed to study material such as newspaper article, a video, or a story and then are asked to recall the story first individually, then jointly as a pair, and finally, again, individually. Analysis of the content of the final individual recall reveals how the processes that unfold during joint remembering affect participants' individual memories.

Employing this experimental paradigm to study how individuals influence each other's memories in a conversational setting resulted in the discovery of three important psychological processes. First, there is a significant literature on the social contagion of memory. According to this research, information that only one participant knew emerges in conversations and is taken over by the other conversational participants (Roediger et al., 2001). Critically, the contagious information is often misleading, that is, an inaccurate recollection of the past. Second, information mentioned in the conversation is reinforced through practice effects (Karpicke and Roediger, 2007). That is, repeatedly listening to certain pieces of information will make this information more memorable, and more likely to emerge in future recalls for both speakers and listeners. And third, information that is not mentioned in the conversation is more likely to be forgotten by the interactants (Cuc et al., 2007). Critically, information that is related to what is discussed in the conversation is more likely to be forgotten than information that is unrelated to what is discussed. This phenomenon is known as retrieval induced forgetting. Information that the speaker recounts in the conversation results in induced forgetting in his/her related memories (*within-individual retrieval-induced forgetting*, or WIRIF), and also in the listeners' related memories (*socially shared retrieval-induced forgetting*, or SSRIF). Given that in most situations WIRIF and SSRIF occur simultaneously, they lead to forgetting of the same material between speakers and listeners, and thus increase in the overlap among conversational participants' memories is reached. By and large, all three discussed effects have cumulative effects insofar as mnemonic convergence is concerned.

Group Processes

Instead of focusing on the influence one person has on the memory of another, some researchers have examined how group processes affect what people remember as the group attempts to jointly recount the past. Several findings emerge. First, individuals distribute the task of remembering, a process called transactive memory (Wegner, 1987). Couples, for instance, tacitly coordinate during the memory task, such that each member of the pair focuses attention on a subset of the material to be remembered. They use their knowledge of the other interactant to infer what information they should pay attention to and later remember. It is this knowledge, an essential aspect of a transactive memory system, which allows for increased group recall performance.

Second, by analyzing a group's memory performance, researchers found that a group remembers more than any individual member on their own (collaborative facilitation), but less than the sum of the nonoverlapping individual memories remembered in isolation by group members (collaborative inhibition). Several explanations have been proposed for these group phenomena (for a review, see Hirst and Echterhoff, 2012). Suffice it to say that the surfacing of memories in joint remembering was found to impact group members' memories making them more similar to one another's (Barnier et al., 2008; Rajaram and Pereira-Pasarin, 2010).

Information Propagation and Extension to Social Networks

Most of the research reviewed under this section has focused on dyadic, or small group interactions. We know, however, that mnemonic effects go beyond these small group interactions. For instance, in an experiment designed to understand information propagation in social networks Harber and Cohen (2005) studied how a morgue visit by 33 students propagated in conversations in their social networks and reached nearly 900 people within 10 days. The finding that the more emotionally arousing one's experience the deeper into one's social network the information spreads, showcases the importance of individual processes in as much as propagation is concerned. This emotional contagion effect is due to the fact that the individual is more likely to talk about emotional material in vivid terms, which might make the information more likely to propagate (Berger and Milkman, 2012; Sperber and Hirschfeld, 2004).

Following up on the idea that the networks people are embedded in are critically important when it comes to understanding collective phenomena, recent investigations have started to reveal how cognition interacts with structural features of the network to impact mnemonic convergence. Coman et al. (2012), for instance, implemented the results of their empirical studies on conversational influences on memory into computer simulations. They used agent-based computer simulation, a method that allows for the creation of agent societies, akin to human societies. By manipulating the characteristics of agents (e.g., memory, identity) and their interactions (e.g., the degree of mnemonic influence), Coman et al. set out to study the parameters that affect mnemonic convergence. They showed that the degree of dyadic influence, network structure, network size, and number of conversations are all critical factors when it comes to creating collective memories. This work advocates for an approach that seeks to establish general principles by operationalizing collective memory and examining the contribution of cognitive mechanisms as well as the social dynamics to the emerging collective representations.

While acknowledging that studying large groups of interacting individuals is challenging from both practical and methodological perspectives, researchers interested in collective dynamics have made meaningful progress in understanding the spread, stability, and the convergence of memories within both small and large communities.

Collective Memory as a Product: The Role of Identity

Even though the relation between collective memories and identity is widely theorized within the social sciences, it has not yet been explored in much detail in the psychological literature. This is surprising, inasmuch as identity, and particularly collective identity has been the topic of empirical investigations in social psychology for much of its history (Ellemers et al., 2002). The exploration of the relation between collective memory and collective identity has been successfully undertaken, however,

by a small group of psychologically minded sociologists. They employ an aggregation method to study collective memory. For instance, Schuman and his collaborators asked participants to name important public events that happened during a period of 50 years. By computing the proportion of the sample that remembered public events within this time span, they conclude that different cohorts have different collective memories. Events that happened when participants were in their adolescence and young adulthood were much more likely to be mentioned as important when compared to events outside of this critical period. The study of individual autobiographical memories reveals the same pattern, referred to as the *reminiscence bump* (Berntsen and Rubin, 2002). Critically, the explanation that applies to both the individual and public reminiscence bumps is that identities become crystalized during this transitional period in one's life, which facilitates the integration of these events into our identities (Brown et al., 2009).

Linking process and product, and building on Bartlett's schemata theory, Wertsch (2002) proposed that culturally dependent schemas lead to the emergence of different collective memories for different cultures. He proposed that individuals employ schematic narrative structures to guide remembering of public events. For instance, the narrative structures that Russians employ when remembering the past start with a context in which Russia is unrightfully attacked by outsiders, then, overwhelmed by them, and finally, through courage and solidarity, the Russians triumph over their enemies. This schematic narrative structure is then, employed by individuals to make sense of and remember past and present events. This approach is one that proposes an explanatory process to the observed collective memories.

In order to explore the process–product link, scholars have started to take seriously the claims that collective representations are distributed in the population and that they change over time (Michelian and Sutton, 2013). Attempts to operationalize collective memory in a positivistic manner would not only provide a framework in which these claims could be rigorously investigated, but would also advance our current understanding of the factors that drive the emergence of collective memory.

Conclusion

This article presented the historical background as well as recent empirical advances in the psychology of collective memory. After tracing the roots of the psychological investigations of collective memory to Bartlett's visionary approach to memory, I have succinctly presented the current empirical work on the psychology of collective memory.

The advances in this burgeoning field show that integrating psychological insights into approaches aimed at understanding large-scale dynamics is a promising avenue for research. The scope of this investigation is larger than simply understanding the formation of collective memories, since these theoretical and methodological advances could be used to construct a scaffold for understanding how communities mobilize their identities, how they make decisions and solve problems collectively. Scholars have already convincingly made the case for an approach aimed at bridging between micro and macroprocesses when it comes to understanding culture (Cole, 1996; DiMaggio, 1997). Even though approaches that psychologized culture to an extreme, such as Parson's attempt to study it as a collection of beliefs, values, and norms, are cautioned against as unrealistic (DiMaggio, 1997), an effort to identify potential bridges between micro and macroprocesses is certainly within the reach of social sciences today. A social interactionist approach in which both individual cognition and social dynamics are interactive units of a system has produced, as shown in this contribution, meaningful advances within the social sciences.

Abstract

Collective memories are shared representations of a group's past based on a common identity. Social psychological approaches of collective memory have addressed their antecedents and functions. Their formation is affected by cognitive and emotional factors, but it takes place in the context of human interactions with other humans or with cultural artifacts. They are shaped by, and transmitted through, narratives. Because they intervene in the definition, maintenance, and mobilization of social identities, they have a strong impact on intergroup relations. Collective memories influence the present, but they are also influenced by present psychological states and needs.

Introduction

Through the expression 'collective memory,' a psychological faculty – memory – is attributed to a social group, whether small (a family, a group of friends) or large (a whole nation). Collective memories are instrumental in defining, maintaining, and mobilizing social identities. As a consequence, they are involved in intergroup relations, particularly in intergroup conflict and reconciliation processes. For example, Barack Obama began his second inaugural address (21 January 2013) by reminding the principles of equality and freedom on which the USA were founded. Then he emphasized the continuity of their history: "Today we continue a never-ending journey, to bridge the meaning of those words with the realities of our time" (White House, 2013). And he listed some of the lessons learned from this history. The first one was about racial equality: "Through blood drawn by lash and blood drawn by sword, we learned that no union founded on the principles of liberty and equality could survive half-slave and half-free." This was an allusion to Abraham Lincoln's second inauguration address: "until every drop of blood drawn with the lash shall be paid by another drawn with the sword." Through this speech, Obama depicted the USA as a united people that, beyond social and racial divisions, share the same identity and strive to achieve the same goals. He did it by drawing on the collective memory shared by Americans and by stressing the continuity of the nation, as well as by casting himself as the continuator of the founding fathers of the nation. Thereby, he asserted his legitimacy as the President of the USA and tried to mobilize Americans toward the realization of his political agenda.

Most scholars refer to the sociologist Maurice Halbwachs (1980, 1992) as the founding father of collective memory studies, although he did not coin the term (Olick et al., 2011). Halbwachs was influenced both by Emile Durkheim's sociology of collective representations and by Henri Bergson's philosophy of subjectivity. Accordingly, Halbwachs tried to conciliate an individual-based and a collective-based accounts of collective memory. But Halbwachs defended different, apparently incompatible, theses on the nature of collective memories. In *The collective memory*, he wrote "it is individuals as group members who remember" (Halbwachs, 1980: p. 48) whereas, in *The social frameworks of memory*, he stated "it is only natural that we consider the group in itself as having the capacity to remember" (Halbwachs, 1992: p. 54). Thus, Wertsch (2002) distinguishes two interpretations of collective memory: the strong and the distributed versions. According to the strong version, groups have memories above and beyond the minds of group members. Wertsch views this version as a metaphor that can be useful in some circumstances – i.e., when dealing with very cohesive social groups – but should not be taken literally. In contrast, the distributed version assumes that group members share some representations of the past, without positing that the group itself has a memory. Among distributed accounts of collective memory, one can further distinguish homogeneous and complementary variants. The homogeneous variant assumes that all group members share the same representation of the past, whereas the complementary variant posits that group members hold different representations, but that these are coordinated to form a system made of complementary pieces.

Frederic Bartlett (1932) is generally credited for having introduced collective memory in the field of psychology. In Remembering: a study in experimental and social psychology, he defended a distributed account of collective memory, and criticized Halbwachs for having reified the concept. However, according to Bartlett, remembering is social in nature. Far from being enclosed in the individual's mind, it is a skilled activity that takes place in the framework of human interactions (Sutton, 2008). This activity does not amount to retrieve information that was previously stocked in the individual memory system, but rather implies an active reconstruction of memory traces as a function of the present situation. More precisely, it is the interaction between schemata inherited from our cultural background or from our personal experiences and the situational context that determines this reconstruction. This reconstruction is therefore influenced by the social context in which remembering takes place, which implies that representations of the past can be distorted, both at the individual and at the collective levels. Indeed, social groups such as nations 'flatter and deceive themselves' (Baumeister and Hastings, 1997).

As an object of scientific inquiry, collective memory lies at the crossroads between behavioral and social sciences. Historians, sociologists, political scientists, philosophers, cultural scientists, anthropologists, and philologists, as well as psychologists have contributed to develop what has been referred to as 'memory studies' (Olick et al., 2011). Somehow paradoxically, the contribution of psychologists, and particularly of social psychologists, appeared relatively late in the history of this movement, and it still represents only a small portion of the bulk of studies and theoretical developments on collective memory. In psychology, interest in collective memory and social representations of history sprang in the 1930s with the work of Bartlett (1932) then waned only to regain some visibility from the 1990s on. However, as we shall see, this contribution has been continuously increasing ever since and, as we shall argue, this contribution is significant.

Psychologists have addressed different categories of questions regarding collective memory: how do collective memories form? What are their social psychological functions? And what is their influence on intergroup relations?

The Psychological Antecedents of Collective Memory

Cognition

Coman et al. (2009) anchor their approach of collective memory in cognitive psychology, in line with Bartlett's interactionist and constructivist stance. They reckon that collective memory should not be conflated with individual psychology. However, they emphasize that collective memories should not only be studied at the collective level – publicly available symbols maintained by society – because it is the interplay between these public symbols and individual psychology that makes these memories collective. This interplay is necessary because of the very nature of human memory. Coman et al. advocate a social interactional approach to memory according to which internal and external factors should be considered: "When it comes to the study of memory, the claim would be that, in order to understand how a person remembers what he ate last night, a researcher needs to consider not only the neural mechanisms underlying memory, but also, for instance, the visual cues in the environment, such as the pile of dishes in the sink" (2009: p. 127). Human beings reconstruct their memories by using cues available in their environment. For example, bartenders use the shape of glasses as cues to remember complex orders. They place the appropriate glass on the bar when they receive the order; the presence of different glass shapes then guides their memory. The use of social artifacts is seen as a response to the limitation of human mnemonic capacities. As Sutton (2008: p. 220) pointed out, "it's just because isolated items aren't stored atomically in the brain that our relatively vulnerable biological memories are supplemented by more stable external scaffolding. Brains like ours need media, objects, and other people to function fully as minds." Likewise, society restructures the world so that the group better remembers. For example, the Washington Lincoln memorial was built in order to guide people's remembering of this president as a godlike figure. Thus, the memories of people who visited the Lincoln memorial are influenced in a similar way, which gradually changes their collective memory. Thus, the interactions that group members have with social artifacts shape their memories (Coman et al., 2009).

With his 'lay historian' metaphor, Klein (2013) also advocates for the taking into account of the role of cognitive processes in the formation of collective memory. Lay people are regularly facing the necessity of explaining the past, either for themselves or for others. Klein parallels the construction of lay knowledge about the past with the three steps involved in historical research: archival (access to knowledge), explanatory (elaboration of causal reasoning about past events), and representational (elaboration and communication of a representation adapted to an audience). Cognitive or sociocognitive processes intervene at each of these steps when lay historians form their historical knowledge. These processes may lead to biases, thus hampering the epistemic function of collective memory. For example, people's evaluation of the truthfulness of testimonies depends on their evaluation of the reliability of the source: they tend to use ready-made heuristics when the source is deemed trustful, or adopt a critical posture when it is not, thus influencing the archival step. At the explanatory step, other cognitive phenomena may then interfere. For example, people generally try to explain unexpected or unpleasant events, thus neglecting events that appear to follow the 'normal course of history' or that are pleasant. They also underestimate chance and overestimate causal explanations. In addition, they often fall prey to the retrospective illusion or hindsight bias: when the outcome of a sequence of events is known, people tend to overestimate the probability of that particular outcome over all other possible ones. This might lead to reconstructing the sequence of events in order to explain this outcome through a coherent narrative that logically leads to it, thus obliterating elements of the past that do not contribute or contradict this narrative. Finally, social cognitive biases can also interfere at the representational step, when a representation of the past is communicated to others through narration. Explaining is always explaining something to someone. Therefore, the representation that one communicates may be influenced by the characteristics of the audience one is addressing. A study showed that participants provided different explanations of a mass murder as a function of whether they addressed a personality psychologist or a nonspecialist: their explanations were more dispositional in the former than in the latter case. Thus, people adapt their message as a function of the way they perceive their audience. In brief, various cognitive and social cognitive processes known by psychologists may shape laypeople's understanding of the past and, indirectly, contribute to the formation of collective memories.

Collective memory approaches anchored in cognitive psychology or social cognition already pay due attention to interactional factors. Some approaches have gone a step further in that direction by stressing the importance of conversations in the formation and transmission of collective memories.

Conversation

According to Middleton and Edwards' (1990) discourse-analytical approach, in the course of conversations, people

coconstruct their memories or contest other people's accounts of an event. Versions of events are seen as pragmatic speech acts deemed to achieve rhetorical functions, so that a version cannot be taken as a person's real memory. Collective remembering is then studied as a joint activity rather than as the product of this activity: memory is the act of remembering and forgetting together.

Coman et al. (2009) also contend that conversations play a pivotal role in the formation of collective memories. People often talk about past events that had important consequences for their social group. These conversations can thus be instrumental in the spreading of memories across the group. One speaker, especially if she is seen as an expert, may influence a listener's memory that could, in turn, influence another listener, and so forth. For example, individual memories of family members were collected before and after a conversation about a story they had just read. Individual recollections were much more similar after than before the collective remembering, and story details that were shared during the conversation were disproportionately included in individual accounts of the story. Conversely, collective remembering can also lead to the forgetting of some elements of a narrative: listening to someone who communicates some items of a narrative, but fails to communicate other related items, facilitates recall of the communicated items while inhibiting the recall of unmentioned ones (Stone et al., 2010).

Narratives

Bartlett (1932) studied the formation of collective memories by asking participants to recount a story they had just read to others. According to Jerome Bruner (1990), human thought is organized by storytelling, but this cognitive mechanism is validated and maintained socially. As accounts of events involving some temporal or causal coherence (Laszlo, 2013), narratives have been viewed as means *par excellence* for forming and transmitting collective memories. In cultures with literacy, these historic narratives are mainly conveyed through texts. Written accounts of the distant or close past of nations are very influential in shaping and maintaining a sense of national identity. These narratives are not univocal: they are debated and contested in the public sphere, where several versions of the same events often compete (Jovchelovitch, 2012; Reicher and Hopkins, 2001). But this very process of contestation ensures that the memory of the event is kept alive. Laszlo (2013) has studied the historical trajectories of nations as remembered by laypeople. For example, these studies showed that the history of Hungary is remembered as a story of grandeur (anti-Ottoman, then anti-Austrian fights) followed by decline (Trianon Treaty, wars), then by a slow but incomplete redress (end of Soviet rule). Hungarian collective memory is familiar with the 'First victory, then failure' pattern, but not with the 'Failure, then victory' one, which prevents Hungarians from making sense of the fall of the Berlin wall as it rather belongs to the latter.

Emotions

When an event affects the lives of large numbers of individuals, it triggers emotions. As these emotions are shared among group members, they may facilitate the formation of collective memories about that event. Hence, according to Pennebaker and Banasik (1997), collective events are more likely to lead to collective memories when they bring social change; are emotionally loaded; elicit social sharing; are socially rehearsed by the mass media; and are associated with collective behaviors such as rituals, demonstrations, or commemorations.

Flashbulb memories are vivid recollections of the personal circumstances in which one receives the news about a shocking event. For example, many people remember how was the weather, where they were, or what tune was playing on the radio when they heard about the 9/11 attacks. Research on flashbulb memories concentrated quasi exclusively on negative – often violent – collective events, such as the assassination of political leaders, terrorist attacks, disasters, and catastrophes (Paez et al., 2009). These events prompt emotions in most, if not all, members of a population. Berntsen (2009) has shown that social identity relevance, rather than personal relevance, was central for the formation and maintenance of flashbulb memories. Flashbulb memories and collective memories share many characteristics and are probably two ways of studying the same phenomenon (Paez et al., 2009).

Emotions are therefore crucial determinants of the formation of collective memories, but their role extends far beyond this formation phase. Collective rituals are particularly effective in maintaining collective memories. To be sure, commemorative ceremonies are designed for this very function. Those rituals, through their form and content, are effective in reminding the event through the repetitive reactivation of the cognitive representation. However, rites are more than reminders, they are reenactments of the event (Connerton, 1989) and, as such, they also engage bodies. In collective emotional gatherings, people perform the same gestures, adopt the same postures, sing the same songs at the unison. This synchrony leads to an important social sharing of emotions, to the point of eliciting feelings of 'identity fusion.' This experience then revives the common identity and the beliefs associated with it (Paez and Rimé, 2014).

The Social Psychological Functions of Collective Memory

Cognitive, social interactional, and emotional factors thus play a role in the formation and maintenance of collective memories. Beyond the question of their formation, social psychologists have devoted much attention to their functions. Rather than providing an accurate account of the past, their main function is to provide a *usable past* (Wertsch, 2002); a representation of the past that can fulfill some role in the present. Collective memory "retains from the past only what still lives or is capable of living in the consciousness of the groups keeping the memory alive" (Halbwachs, 1980: p. 80). According to psychologists, collective memories are kept alive if they meet the needs and motivations of group members. These needs have been described as epistemic – providing a clear representation of the group's past – and/or identitary – defining the group's identity. Social identity (Tajfel and Turner, 1986) and social representations theories (Moscovici,

2008), either independently or in combination, have often been mobilized in this framework.

Social Identity Approaches to Collective Memory

Tajfel and Turner (1986: p. 16) defined social identity as "those aspects of an individual's self-image that derive from the social categories to which he perceives himself as belonging." Collective memory fulfills various functions with regard to social identity (Klein et al., 2011). First, collective memories contribute to the group's definition. According to Liu and Hilton (2005: p. 537), "History provides us with narratives that tell us who we are, where we came from and where we should be going. It defines a trajectory which helps construct the essence of a group's identity, how it relates to other groups, and ascertains what its options are for facing present challenges." Representations of the group's past, which are constantly renegotiated as a function of the present situation, thus provide content to the social identity. In addition, these representations have a normative function as they define how that group should behave. Paralleling Malinowski's views on myths, Liu and Hilton contend that social representations of history serve as 'charters' that define how the group should react to a present situation, because group members draw a 'moral' from their interpretation of a past event. Beyond these cognitive and normative aspects, the simple fact that those representations are shared brings a sense of cohesion among group members. Thus, this imagined past simultaneously creates a 'horizontal' solidarity between contemporary group members and a 'vertical' solidarity with past and future members of the group. In brief, sharing representations of the group's past confers psychological reality to that group.

In particular, representing the group as continuous through time facilitates identification with it (Sani, 2008). Conversely, presenting the group's history as discontinuous may elicit collective angst regarding the group's future, which can lead to group protective attitudes, such as opposing immigration (Jetten and Wohl, 2012; Smeekes and Verkuyten, 2013).

Second, collective memory contributes to set the group's value. According to Social identity theory (Tajfel and Turner, 1986), people are motivated to hold a positive view of their group because their social identity is an intimate part of their self-concept. The group's value is assessed through intergroup comparisons. As a consequence, one needs to belong to a group that compares positively with relevant out-groups in order to derive a positive collective self-esteem. A group's past – its successes and failures; its moral or immoral actions – hence contribute to defining its relative value. Social groups thus compare their respective pasts, and generally strive to derive a positive sense of their identity through this comparison. This helps explain why collective memories are often biased toward positive accounts of the in-group's past and/or negative accounts of out-groups' actions in history (Baumeister and Hastings, 1997). In addition, it accounts for the fact that some representations of the group's past – such as reminders of past misdeeds – elicit strong defensive reactions (Branscombe and Doosje, 2004).

Third, collective memories can be used for legitimizing past, present, or planned actions of the group. For example, Serb nationalists referred to memories of the Kosovo battle in 1389, after which the Serbs had lost control over the Kosovar territory, in order to legitimize the deportation of Muslim Kosovars in the 1990s.

Fourth, collective memories can be used in order to mobilize members of a social group to accomplish a particular collective – often political – project in the name of their shared identity (Reicher and Hopkins, 2001). For example, the Congolese leader Patrice Lumumba adapted his discourse as a function of the audience he was addressing: in front of a Congolese audience, he would represent the history of colonization as undermined by the Belgians' cupidity and contempt whereas, in front of a Belgian audience, he would emphasize the friendship that the colonial experience had allowed to build between the two nations. Far from being a simple example of opportunism, this apparent lack of coherence actually reflected a stable political project, which demanded different actions from different actors. Hence, he had to mobilize the Congolese against the paternalistic colonial ideology, as well as make sure that the Belgians would collaborate with the new independent State (Klein and Licata, 2003).

Collective Memory and Reconciliation Processes

The management of collective memories of a past conflict is crucial to the quality of the present and future intergroup relations. Indeed, narratives shared inside the implicated groups often diverge. Given that social groups are motivated to perceive themselves in a positive way, these narratives are fundamentally selective, including and excluding historical events in order to characterize one's group in a positive way, at the expense of the former enemy's image (Bar-Tal, 2003).

In a postconflict context, the status attributed to a group during the conflict is determinant for the contents of the collective memory. These contents will be very different whether the group is casted as the victim or as the perpetrator in the historical narrative. Thus, if the positive actions of a group allow its members to value, and assert their moral character, its negative actions pose a significant threat to collective self-esteem, especially among highly identified group members (Branscombe and Doosje, 2004).

Memories of past misdeeds committed by the group are therefore difficult to integrate into the group's history. Being casted as a perpetrator group has consequences both within the social group and between social groups. Individuals seek to differentiate themselves from members who have committed negative actions. Therefore, the perpetrator status is associated with important tension, undermining social cohesion within the group. However, this status may also have a positive impact at the intergroup level. Indeed, group members may experience negative group-based moral emotions, such as collective guilt, shame, or regret (Giner-Sorolla, 2012). For example, memories of colonialism have been shown to trigger collective guilt or shame among young generations in formerly colonizing countries (Volpato and Licata, 2010). These aversive emotions motivate individuals to implement acts of reparation toward out-group members (Branscombe and Doosje, 2004).

The victim status also affects the social dynamics within and between groups. This position can be traumatic for the group, and hence also threaten its cohesion. However, if the traumatic event is commemorated – which highlights the common destiny of group members and accentuates distinction from other groups – the integration of past in-group sufferings in collective memory may have the opposite effect and increase social cohesion (Bar-Tal et al., 2009).

Victimhood also involves a competitive component: people draw comparisons between the sufferings of the groups involved in the conflict (Noor et al., 2012). This competitive victimhood implies a vision of the suffering of one's group as being more important and less legitimate compared to that of the out-group, and represents a strong obstacle to intergroup reconciliation.

However, perpetrator and victim statuses are not always incompatible. Indeed, in intergroup conflicts such as wars, and especially civil wars, group members are often involved in violent actions against the out-group, while themselves undergoing violence. In that case, the recognition of one's group's victim status might prevent group members from implementing reconciliation mechanisms. Indeed, perceived collective victimhood tends to inhibit empathy toward the out-group and provides an opportunity to discard any responsibility in the conflict (Bar-Tal et al., 2009). It then tends to reduce propensity to experience collective guilt. Yet, victimhood can be reframed: group members can include their former enemies into a common group, thus sharing a common identity of individuals having suffered from the conflict (Vollhardt, 2012). This inclusive view of victimhood has the opposite effects on intergroup relations: it leads to more empathy and increases willingness to forgive the out-group.

Statuses of victim and perpetrator are associated with a gain or loss of power in intergroup dynamics. In the aftermath of the conflict, the victimized group may appeal to the international community to recognize its status, or to obtain compensation from its former opponent, which can increase its relative power. The relationship between collective memory and power is thus mutual: the dominant group often has control over the official memory, particularly through public commemorations. In contrast, low-status groups strive for recognition of their status in the official narrative. Therefore, discourses about memory should be interpreted as a function of the group's current position and of its objectives (Reicher and Hopkins, 2001).

Collective Memories as Social Representations

The way a social group relates to its past can be envisioned in two different manners: collective memories are either depicted as weighing on the group's present, or as being influenced by the group's present (Prager, 1998). The past can be undergone or it can be chosen. For example, one can view memories of a collective trauma as bearing on the present, independently of people's will. Survivors of genocides and their descendants have to live with these sore memories, as they are included in their social identity. However, collective memories can also be tailored to fulfill current identity needs, or to legitimize behaviors. This rejoins Bartlett's contention that "with the individual as with the group, the past is continually re-made, reconstructed as a function of present interests" (1932: p. 309). For example, after the 9/11 attacks, American participants prompted to cite significant events of the last 70 years mainly listed events involving war or an attack against an American institution (Schuman and Rodgers, 2004). This suggests that people remember events that are in line with their present mental state: present to past. However, representations of the past can also influence the present. Indeed, drawing analogies between the 9/11 attacks and the Munich agreement of 1938 or to Pearl Harbor yielded an understanding of these attacks through the prism of a war metaphor. In turn, this metaphor helped legitimizing attacks of Afghanistan, then Iraq (Kruglanski et al., 2007). Thus, representations of history influence the interpretation of current situations: past to present. This example suggests that both directions of influence are part of the same global dynamic: present situations influence the choice and interpretation of particular memories, which in turn are used to make sense of present situations and to tailor people's attitudes and behaviors.

Moscovici's social representations theory (2008), provides a theoretical framework that accounts for both directions of influence. It posits that social representations form through two processes: objectification and anchoring. Objectification is the process through which complex, often abstract, concepts are gradually transformed, through social exchange, into concrete, visual images. Anchoring relates to the integration of a new knowledge into a group's preexisting knowledge system. The latter process is useful for understanding how the past weighs on the present (Liu and Hilton, 2005) as – already shared – collective memories of past events are used for making sense of current events. The objectification process is useful to account for the fact that the past is continually reconstructed as a function of present stakes (Clémence, 2002). Hence, contemporary attitudes, norms, and values are projected onto past events and historical characters in a process of objectification. This creates the illusion that current states of mind or ideological choices are based on objective historical facts, which endows them with legitimizing power (Klein et al., 2011). Finally, these past events or figures, which actually objectify present concerns, can then serve to anchor new knowledge. As Jan Assmann (1997: p. 9) pointed out "The past is not simply 'received' by the present. The present is 'haunted' by the past and the past is modeled, invented, reinvented, and reconstructed by the present."

Abstract

The concept of collective memory introduced by Maurice Halbwachs is one of the key concepts to understand how a society maintains its order and how social change occurs. In this sense, the sociology of collective memory is not a simple branch of sociology and can contribute to an elaboration of general social theory all the more so as late-modern society is becoming the age of preservation when even negative memory like war experiences becomes an object of preservation and that of globalization politics of memory occupy an important or even primordial place.

How can social order be maintained? This is indisputably one of the most crucial questions in sociology. There are two approaches to answer this question. One is to focus on the durable form of society by resorting to terms like social structure or social system to designate the continuation of social order. Another approach is to try to understand by which means a society can last. Collective representation introduced by Émile Durkheim is one of the founding concepts of this approach (Durkheim, 1937). According to Durkheim, collective representation refers to a symbol having common-shared meaning to members of a social group or society. Sociology of collective memory introduced by Maurice Halbwachs, one of the disciples of Durkheim, is on the line of Durkheimian sociological theory.

Collective Memory in Halbwachs

Memory is a complex totality of knowledge and image and, generally, is considered as belonging to the individual. For Halbwachs, however, individual memory is not completely closed insofar as it is constructed through interactions with others. Individual memory is, then, influenced by the collective representation of the past. In this sense, there is no individual memory as such. Halbwachs designates this collective representation of the past as collective memory.

Jeffey K. Olick remarked quite rightly that collective memory in Halbwachs indicates two district sorts of phenomena: socially framed individual memories, and collective commemorative representations and mnemonic traces (Olick, 2007: 20). In the first part of his *The Social Framework of Memory* (Halbwachs, 1925), Halbwachs tends to discuss on the collective memory from the point of view of an individual. In particular when he treats familial memory, his argument focuses essentially on the way in which an individual constitutes his/her memory in relation with others, and through what he calls *framework*. Framework gives opportunities to remember the past related to one's individual life. Some members of the group and/or some important events constitute a framework which offers a reference point for remembering. Collective memory defined as such is not well demarcated. It is something uncertain and difficult to comprehend. Furthermore, collective memory changes with time, because those who compose the group, change. In other words, it is closely linked to the living past of those who compose the group. If the past loses this vivacity for the members of the group, it will be outside of the collective memory.

However, when Halbwachs analyzes religious collective memory, he treats this as something quite distinct, insofar as religious memory belongs to a group and is considered as fixed once and for all by the group. For example, the Church has its own memory which is religious doctrine. It seems to the members of the Church that the doctrine is unchanging. Christians believe that the memory of Christians faithfully keeps the life of Christ. In fact what they believe is not unchanging, because collective memory is essentially a reconstruction of the past. Halbwachs (1971) goes so far as to say, in particular, in his study on topography and religious memory, that knowledge of what was original is secondary, or even unimportant. Collective memory considered in this way comes close to collective representation, or even becomes synonymous with collective conscience. Religious memory considered in this way is more than a simple aggregation of individual memories.

Past in the Present or Past Constructed by the Present

The English-speaking and German-speaking tradition of social theory uses the term, *knowledge* rather than the concept of memory in the sense that it, in particular, takes an interest in the process of cognition and comprehension. George Herbert Mead pointed out that the past is in the present (Mead, 1932). He affirmed in a similar way as Halbwachs that the past is reconstructed by the present point of view. An individual thinks of the past always only at present and the knowledge about the past determined by the present may change (Adam, 1995: 81). Alfred Schutz inspired by the phenomenology attempts to show how an individual forms his/her stock of knowledge. He uses the term, 'retention' to designate the process by or in which an individual constitutes his/her stock of knowledge through his/her experiences. He also mentions the world of 'predecessors' who play a role in the formation of the knowledge on the 'social world' (Schutz and Luckmann, 1973).

Mead and Schutz as well as Halbwachs emphasize the constitutive aspects of the past while Michael Polanyi treats of unconscious acquirement of knowledge by resorting to the concept of 'tacit knowledge.' The essence of tacit knowledge

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32191-2

lies in Polanyi's statement, "We can know more than we can tell" (Polanyi, 1966: 4). That is, knowledge is not limited to that which we can consciously analyze using language; knowledge perceived physically precedes it, and Polanyi considered that this knowledge is more fundamental. For instance, students preparing their sociology graduation theses hear other students' interim reports about their theses and feel that they are interesting, but they cannot explain why the reports are interesting. This is because the students are not focusing on and analyzing the values of the specific themes of the theses and the problems they propose, but are simply making intuitive judgments. To use a term coined by Polanyi, the students have already 'internalized' their sociological knowledge. To wit, the knowledge as yet without form is indwelled, but the students are not aware of it, and therefore the students can only judge whether sociological problems have been constructed or not intuitively. Polanyi's theory illustrates that the indefinite portion of knowledge that exists prior to being given form by language (including things such as intuition, gut feeling, and senses) holds considerable significance for everything from our daily activities through to scientific discovery. Part of human intellectual work is indefinite and cannot be given form, and that the acquisition and creation of knowledge is impossible without this tacit part.

Nonetheless, Polanyi placed too much emphasis on the point that knowledge is created by the individual and ignored the relationship between the individual person and the external environment. Individuals act within a predetermined environment but are not necessarily aware of the relationship between that environment and their actions, and because people do not always act based on the most rational judgments, it is not given that they can clearly express the reality in which they exist using their own expressions.

There are two different ways of thinking about the past. One emphasizes the constitutive aspects of the past. The other insists on the unaware aspects of the transmission of the past. If there exists a tacit part of knowledge, this part has to be socially constituted and accumulated. The tacit knowledge thus presuppose some accumulative dimension. Tacit knowledge understood in this way comes close to the concept of 'habitus' in the social theory of Pierre Bourdieu. Habitus conceived by Bourdieu allows a given situation to be appropriate without any reflection, since habitus embedded in our body makes it possible to sustain the social structure (Bourdieu, 1980). In other words, by means of habitus, repetitive and unconscious practice in daily life assure the 'reproduction.' This question of cultural practice or quite simply of tradition in the sense given by Edward Shils (1981) is distinguished from that of collective memory insofar as tacit knowledge and habitus constitute an unconscious and corporal way of cultural transmission. Nevertheless, corporal transmission of culture analyzed by Bourdieu may supplement the study in sociology of collective memory in the strict sense of the word.

History and Collective Memory

The constructive nature of collective memory pointed out by Halbwachs gives rise to numerous empirical studies in sociology and history. However, according to Halbwachs, collective memory is different from history even if history influences the formation of collective memory, because collective memory holds only a part of the past that is still alive in the conscience of the group. On the contrary, history chooses important events and tries to give these events an order to simplify them for the didactic purpose. Traditional conception of history defined as such by Halbwachs is revised nowadays insofar as Annales School inspired by the Durkheimian school brought a great change to the conception of history. The title of its journal, *Annales d'histoire économique et sociale*, insists on the importance of economic and social history and shows well the nature of the Annales School. Lucian Febvre and Marc Bloch, two founders of the Annales School, declared that historians should find problems from the interests of the present to write a living past. This indicates they shared the same problematic as that of their intimate colleague at Strasbourg University, Halbwachs. In this sense, history comes up to or surfaces in the collective memory. The difference lies in the fact that collective memory is more likely to fade out with the disappearance of those directly concerned.

Structuralism also contributed to the change of perspective by moving away from the modern, straight-line view of history and questioning the origins of phenomena that can be explained by the existence of certain structures. While, by definition, the structures behind the phenomena may lack any historical factor, the fact is that every phenomenon has an origin. Lévi-Strauss (1962) asserted that rituals of commemoration were held to reproduce the past in the present to resurrect mythological origins in the present.

The idea of collective memory introduced by Halbwachs and the Annales School is picked up again from the 1970s. The historian Pierre Nora notes that modern society is losing the sense of memory and needs to actively set up institutions that will allow it (society) to keep its memories. He designates these institutions as *lieux de mémoire* (site of memory) in French, an expression difficult to translate into other languages. Some institutions developed in modern society play an important role in the reconstruction of collective memory. Public institutions like archives, libraries, and museums are thus established since the nineteenth century. Important events are commemorated, anniversaries celebrated, and monuments are constructed to remember these events. Autobiographies also offer *lieux de mémoire* that historians can explore.

The same idea can be found in its embryonic stages in Halbwachs; One of the frameworks that orients that the constitution of memory is spatial (Halbwachs, 1925: 97). Memory is closely related to a particular space, for example, a room, a garden, a corner of a street etc., all of which are familiar and gain an affective value and allow us to remember the past. However, the attempt of the historian has to be distinguished from that of the sociologist; the historian makes historiographies on institutions for remembering; the sociologist, on the contrary, insists on the constructive aspect of the memory. The historian tends to accept historical data as such, while the sociologist deliberately brings a critical point of view, given that what the latter is interested in is not to find new historical facts, but to know how an individual or a group

remembers the past. Each group has its traditions and retains its memories on events and persons that made a strong influence on the group. Without these memories shared by the members of the group, the group could not survive. And if some members of the group are influenced by anyone or anything outside of the group, the group reacts in various ways. The group can accept new elements based on memories of the outside openly or in taking the former elements into account. The group can also reject completely new elements to defend its traditions. Conflicts, thus, can occur concerning memory and the reaction of the group can give rise to a change. The sociology of collective memory is, therefore, an attempt to understand how a group maintains its order and how social change occurs. It is not a simple branch of sociology. It seeks for making a sociological theory in which memory plays an essential role.

Social Order and Social Memory

Halbwachs noticed that the memory of ancestors is alive by means of worship. The worship of ancestors is institutionalized, because the living tries to hold the memory of the dead. The ancestor, indeed, plays an important role for the maintenance of the social order. Contemporary of Halbwachs and Durkeimian like him, Marcel Mauss was very sensitive to this issue. He pointed out that "among the first groups of beings with whom men must have made contacts were the sprits of the dead and the gods." (Mauss, 1969: 13) The primordial exchange is an exchange between the living, the gods, and the spirits of the dead. Before Mauss, Friedrich Nietzche made a similar observation in *Genealogy of Morality*:

> …the living generation always acknowledged a legal obligation towards the earlier generation, and in particular towards the earliest, which founded the tribe (abbrev) …There is a prevailing conviction that the tribe *exists* only because of the sacrifices and deeds of the forefathers, – and that these have to be *paid back* with sacrifices and deeds.
>
> Nietzche, 1994: 65

There is an imbalance between a sense of 'obligation' toward our ancestors, and 'us,' and as a result this imbalance becomes a source of control; by demonstrating that one possesses special powers that enables communication with the gods and the spirits of the dead. The order based on the recollection of the dead is therefore established through a never-ending exchange between the living and the spirits of their ancestors.

This mechanism of maintaining order can be described as "the order of recollection" (Ogino, 2006: 59–61).

The order of recollection is the result of man's greatest concern – how to deal with the death of a loved one. In the order of recollection, there is no clean break between family members who have died and those who are still living. Order is sustained by their memories of the dead (their ancestors) who dwell in a sacred place. The dead are seen as protecting the living, and ancestors can at times symbolically communicate with the living. For example, in Japanese Buddhist tradition, the spirits return to *shigan* (the human world) during the *obon* season and therefore the living carry out rituals to receive their ancestors, such as making daily offerings to the *butsudan* (Buddhist altar).

In the order of recollection there is an attempt to restore order and overcome a crisis, by arriving at an understanding of the cause of the crisis by relating it to gods and spirits. A crisis could be a natural disaster such as a flood, or a deterioration of social order triggered by a crime such as theft. *The Legends of Tono* (2008) and its supplement (1989), gathered by ethnologist Kunio Yanagita, shows memories about the area of Tono and its habitants. Whether they are true or not, they show in detail what the habitants remember, i.e., their collective memory. It contains a typical anecdote of theft that demonstrates how the recollection of order functions.

> In the event of an adversity such as theft, the villagers call on the powers of a god named *mitsuminesama* in order to identify the perpetrator. A man called Yoshitaro Sasaki called on the powers of *mitsuminesama* when *watagase* [ceremonial dress made of cotton] was stolen from his house. All the lights in the house were turned off and the *goshintai* [body of god] placed in the *okuzashiki* [innermost room of the house]. Each of the villagers who had gathered in the house then entered the room to pray to *mitsuminesama*. One woman, however, was terrified and refused to enter the room. When the villagers tried to force her into the room, the woman vomited blood and lost consciousness. The villagers therefore concluded that she was the thief. The woman handed over the stolen goods to the villagers that night.
>
> Yanagita, 1989: 101–102

As is clear from this anecdote, the villagers believed that it was *mitsuminesama* and not they themselves who have the ability to solve crimes of theft. Therefore, a series of rituals were carried out in preparation for this, commencing with the welcoming of the *goshintai* by the villagers. This ritual is clearly only carried out "when there are already several suspects" (Yanagita, 1989: 101) and the villagers already have some idea of who is guilty. It should actually be possible to identify the perpetrator without having to carry out such rituals. However, the act of reconfirming the function of the order of recollection through the ritual of identifying the perpetrator is of more significance to the villagers than simply identifying the perpetrator for the Sasaki family and returning the *watagase* to them. Thus, in the event of an incident, the villagers must ask the spirits of the dead for assistance.

Violence was indirectly exerted in this example of theft by forcing the female suspect to vomit blood through the act of ritual. The community exerts violence directly or indirectly against those who it believes have caused a deterioration of order. In each case, the violence is understood to be promoted by a god such as *mitsuminesama* or a priestess who has the ability to communicate with the gods. The exertion of violence is therefore validated because of a god or deity who inhabits a space found beyond the boundaries of the village, or a priestess who possesses the powers to communicate with the gods. The villagers believe the priestess' oracle to be true because she is a mediator who is able to communicate with the gods and the spirits of the dead. This signifies that the villagers are hierarchizing the world that they live in, including places accessible to any person through to those

only accessible to exceptional people or beings. The ability to demonstrate one's power to communicate with gods becomes a source of control. What we can see from the above is that violence is not the trigger for the establishment of order, but that it is the recollection of order that actuates the device that, in turn, enables the exertion of violence in response to a crisis.

Modern Society and Memory

The order of recollection should be inherent in all community. But the more the society is complex, the more the order of recollection is imperiled since the complex society provides more opportunities to come across unknown people who do not share the same memory or memories. Families and communities tend to lose autonomy and submit to the order of the State, designed to be the only peacemaker of different groups facing conflict situations concerning memory. To play this role, the nation-state has tried to construct a new framework of collective memory which Nora called *lieux de mémoire*.

The perception of collective memory and of its constructed aspect by Nora is not a pure coincidence. In fact Henri-Pierre Jeudy pointed out that from 1980s, industrial societies began to constitute their regional and urban ethnology (Jeudy, 1986: 17). Similarly, in sociology a new method based upon life history or life story was highlighted. This phenomenon common to industrial societies was, in part, due to the accelerated innovation in industry, which inevitably caused the social transformation and the loss of 'old' industry and its value; old industrial sites were recognized as cultural heritage to fill the gap. Therefore, we have entered the age in which we are actively, and as exhaustively as possible, trying to preserve as shared heritage the various experiences of people and the culture they have created. This is signaling the arrival of the "age of preservation."

In this age, what is saved is more than just cultural heritage that is recognized as having aesthetic value, or assets from the distant past such as ancient Egyptian mummies. Things that are preserved include events that invoke abhorrent memories that may still be vivid, and that some people may want to quickly expunge, as well as items connected to these. The A-Bomb Dome is registered on UNESCO's World Heritage List, and can be considered one of these. In addition to monuments or memorials of war, other legacies with negative aspects, including abandoned mines that have resulted in environmental pollution and industrial accidents, and buildings from colonial times can be called 'negative heritage.' These differ from the safeguarding of cultural heritage from ancient periods, for which obtaining political agreement is easy, and can cause controversy and political conflict.

If so, this is related to the ambivalent nature of 'negative memory.' On the one hand, people naturally are subject to the urge to forget unpleasant and unfortunate experiences as soon as possible. Even if people are unable to fully forget these matters, they want to remove themselves from them as much as possible. In the event that they are forced to confront sad memories, they try to keep them bottled up deep inside themselves. Feelings such as these mean that people remain tight-lipped about negative memories, and this is tied to the impulse to expunge all items that could invoke them. The former headquarters of the Governor General of Korea in Seoul was demolished because it evoked memories of the former colonial period. When East and West Germany were unified, the first thing torn down was the Berlin wall although a part of it was preserved.

However, even if this negative memory is of an abhorrent past, this also invokes the desire to record that past, and to express it in different ways. At times, people may feel the desire to talk about the negative experiences that were once so unpleasant to put into words. If this is so, it is because at the core of negative experiences are death and memories of the departed. For instance, the experiences described by survivors of the Hiroshima atomic bomb depict a scene of mass death and suffering as told by those who happened to survive by pure chance. The same goes for those describing the massive destruction of the Great Hanshin-Awaji Earthquake in 1995; houses facing each other across a street suffered differing degrees of damage. This kind of experience serves to make survivors aware that a single step in the wrong direction could have ended in their death rather than survival, and the remembrance of those who died shared by the survivors inspires a will to talk about those experiences – even though they are negative experiences – to pass them on to subsequent generations. In other cases, heritage that no longer exist may be reconstructed, such as in the case of the Urakami Cathedral, a part of the Nagasaki Atomic Bomb Museum. In Korea, the former Governor General's headquarters was demolished, but the Independence Memorial Hall of Korea in Cheonan was constructed, showing dioramas that depict torture carried out by Japanese soldiers.

The question of negative heritage by excellence shows how the late-modern society inclines toward the conservation of the recent past including a negative one that people do not necessarily like to remember. We are forced to keep memory even about events we hope to forget. From the point of view of the sociology of collective memory, this is due to the absence of the order of recollection, which allows the living to mourn for the dead. Through the order of recollection there is an attempt to restore order and overcome crisis. This is achieved by arriving at an understanding of the cause of the crisis through attributing it to gods and spirits. Modern society, in contrast, has lost the smooth functioning of the order of recollection. Faced with a secure future transformed suddenly into uncertainty, no solution is available. In this situation, disaster victims tend to regard their experience as 'absurd.' The loss of the loved ones cannot be accepted. It arouses worry when there are not adequate measures against disasters. The late-modern society seeks to find a pertinent system for mourning by means of commemorations, monuments, museums, and the collection of various stories in vain. The impossibility of mourning would be one of the currents issues in sociology of collective memory.

Postmodern Time and Memory

Philosopher Jean-François Lyotard, who proposed reflections on modernity, threw light on the rise of interests about the

collective memory. According to Lyotard (1988), modernity defines the series of events grouped in the name of the universal history of mankind. He holds that modernity must be formed under the philosophy of liberation, i.e., the perception that mankind is being liberated. Of course this philosophy of liberation – "the Grand Narrative" – can be framed in many ways; liberation from exploitation and alienation under Marxism, liberation from poverty by technology and industry under capitalism, and redemption through the love of Christ, are all modern reiterations of the philosophy of liberation.

However, according to Lyotard, the predominance of western European thinking in modern philosophy, which has been dominant for two centuries, is beginning to crumble. This was triggered by Auschwitz. If history was heading toward the liberation of mankind then modern philosophy has no answer for the question of how it was that so many Jews were allowed to be massacred. Thus, while the perception that modern philosophy is powerless becomes more deeply rooted, the hidden underbelly of modern philosophy is being gradually exposed. This two-faced nature of modernity is one of the defining traits of postmodernism. As a result, postmodernism (as has been pointed out many times) does not refer to a new zeitgeist that follows on from modernism; indeed, the very idea is that a new zeitgeist must follow on from modernism is a modernist view of history. Seeing postmodernism as simply a zeitgeist is to deprive the concept of its defining characteristic.

How, then, should we regard postmodernism? Using the example of a modernist painting, Lyotard (1988) said that a painting can only be modern by first being postmodern. For instance, Cezanne sought to create a new art movement by rejecting impressionism. That could be said to be a postmodern move because it came after impressionism, a modern movement. However, for artists like Braque and Picasso, who came after Cezanne, Cezanne was already modern. So, whether it be Cezanne or Picasso or even Duchamp, who came later still, they first had to arrive on the scene as postmodern artists and remain faithful to the modernist philosophy of "questioning everything that came before" in order to be perceived as modern artists. If this is so, then their elevation as modernist masters was consequential rather than intentional, given that, according to Lyotard (1988: 28) "postmodernism is not the end of modernism but the process by which modernism is born."

The interesting thing about Lyotard's postmodernism theory is that whereas modernism gives meaning to the future by defining history as the process of human liberation, postmodernity has no such preassigned standards and is itself the process of creating new standards. Postmodern works therefore do not seek to be evaluated in accordance with preprepared standards; they are a quest for new standards of value. In that sense, the very act of unveiling a new piece of work takes on the appearance of an event in itself; postmodernism is the tendency toward the chaotic and lies beyond the bounds of established standards.

Seeking new standards does not mean making light of the modernism that gave rise to the established standards. Rather, it is the process of questioning the nature of modernity. It could also be said that the very stance of questioning the nature of modernity is postmodern. Based on a positive image of the future in which it is assumed that people will eventually be liberated, postmodernism abandons the sequencing of discrete events and elements under a straight-line historical perspective. Modern awareness positions the past as a 'passé' age that has been surpassed by the present. In other words, whereas, in the modernist view, the past is defined by the present and the present is defined by the future, postmodernism dismantles the historical view and seeks meaning or to express the very process by which meaning is generated. According to Lyotard, it is similar to psychoanalysis. In this treatment, the analyst seeks to understand the sequence of memories that come flooding back without conscious manipulation, as a means of identifying the root cause of the disorder, the memories that the patient has tried so hard to repress. Postmodernism could be said to have a certain historical awareness and, just like the way images from the past come flooding back in psychoanalysis, postmodernism is the fixation on the memories revived when modernist historical awareness is dismantled.

In modernism, there are two perceptions of time. One is that of modern philosophy, in which history is seen as the process of the liberation of mankind. The second is the postmodern view, which moves away from that kind of past-present-future, straight-line perception of time. In the postmodern view, the past exists only as memories. The important thing here is that for modernity to exist, it requires not just the modernist historical view, which draws the schematics of human liberation, but also the postmodern perspective, which questions those plans. The postmodern perception of time does not, however, oppose the modern view of history. Modernity, after all, has both modern and postmodern aspects and would not exist without both of them (Ogino, 2013).

Halbwachs launched the sociology of collective memory as a critical approach to modern society and the overall view of history on which modernity is founded at the age where the modern notion of history was dominated. This challenge of Halbwachs still remains current at the age of preservation where even negative memory becomes an object of preservation and war heritage is considered as 'cultural' heritage and at the age of globalization politics of memory occupy an important or even primordial place.

Collectivism and Individualism: Cultural and Psychological Concerns

Harry C Triandis, University of Illinois, Champaign, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Collectivism is a cultural pattern found in most traditional societies, especially in Asia, Latin America, and Africa. It contrasts with individualism, which is a cultural pattern found mostly in Western Europe, North America, Australia, and New Zealand. The dimension of collectivism–individualism is also a psychological one that has been examined as a personal and social value. This article describes some of the characteristics of this cultural pattern, its geographic and demographic distribution, and its antecedents and consequences. It also describes collectivism as a psychological phenomenon. It ends with an examination of the implications of globalization and economic development for changes in this cultural pattern, which may involve a weakening of some of its aspects. Especially important are the implications of these changes for well-being and social control. An evaluation of this cultural pattern depends on the criteria that one wishes to maximize.

Introduction

Collectivism is a cultural pattern found especially in East Asia, Latin America, and Africa. It is usually contrasted with individualism found in the West, e.g., in Western and Northern Europe, the USA, Canada, Australia, and New Zealand. Any typology is an oversimplification. Societies are not purely individualist or collectivist, but some mixture of the two. The construct is widely used by those interested in studying cultural differences. It is also used to describe the values of individuals in these differing societies.

Among the most important characteristics of this pattern are the following individual orientations:

1. Individuals define themselves as aspects of a collective, interdependent with some ingroup, such as the family, tribe, coworkers, nation, or religious, political, ideological, economic, or aesthetic group.
2. They give priority to the goals of that collective rather than to their personal goals.
3. Their behavior is determined more often by the norms, roles, and goals of their collective than by their personal attitudes, perceived rights, or likes and dislikes.
4. They stay in their groups and prefer these relationships even when the costs of staying in these relationships exceed the advantages of remaining.

These are some of the defining attributes of collectivism. There are as many kinds of collectivism as there are collectivist cultures. To distinguish among collectivist cultures, additional attributes are necessary (Triandis, 1995).

History

The term was first used in political philosophy in the eighteenth century in contrast to the individualism advocated by John Locke and Adam Smith. An early exponent was Jean-Jacques Rousseau, who in his *Social Contract* (1762) advocated submission to the 'general will,' which was conceived as the common core of societal opinion. Georg Fredrick Hegel and Karl Marx also proposed collectivist philosophic systems.

The term was introduced into psychology by Hofstede (1980) in a study of the values of IBM employees in some 80 countries. He found that by summing the responses to value items of individuals from each country, and using the country as the unit of analysis, it was possible to identify a cluster of responses that reflected collectivism and individualism. Triandis (1995) summarized the literature, which used that construct in social psychology, and Kagitcibasi (1997) provided a critical evaluation of the construct. Oyserman et al. (2002) also expressed some concerns about the degree to which this construct has been used to characterize whole societies, without taking variation within societies into account. Triandis and Gelfand (2012) focused on the theory of collectivism.

Historical analysis suggested that collectivism was the typical cultural pattern in many traditional societies (mainly agricultural and pastoral ones, but less so in hunting and gathering societies). Individualism began emerging in England as early as in the thirteenth century. Traces of individualism have also been found in ancient Greece.

Distribution

Within any society there are individuals who behave like persons in collectivist cultures. They are called *allocentrics*, and contrast with those who behave like persons in individualist cultures who are called *idiocentrics*. It is assumed that there are both allocentrics and idiocentrics in every society, but their distributions are different, with more allocentrics found in collectivist cultures. The distinction between collectivism and allocentrism is important because in some cases a phenomenon observed at the cultural level is quite different from the phenomenon at the individual level of analysis.

Collectivism is maximal in relatively homogeneous societies, such as theocracies and monasteries, while individualism is maximal in heterogeneous societies that are very affluent.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24008-7

Thus, there will be few idiocentrics in monasteries and few allocentrics among Hollywood stars.

All individuals have access to cognitive systems that include both allocentric and idiocentric cognitions but they sample them with different probabilities, depending on the situation. For example, if the ingroup is under attack most individuals become allocentric. In the company of other allocentrics the norms for allocentric behavior become salient and individuals are more likely to sample allocentric cognitions. Some situations provide very clear norms about appropriate behavior (e.g., in a house of worship), while other situations do not (e.g., at a party). Individuals will be more allocentric in the former than in the latter situations. When the ingroup can supervise an individual's behavior, norms are more likely to be observed, and the individual will be more allocentric. When individuals are asked to think for 2 min about what they have in common with their family and friends they are likely to sample more allocentric cognitions. Situations are more important than the personality of individuals as determinants of allocentric behaviors.

Collectivism can appear in all or none of the domains of social life. For example, it can be found in politics, religion, aesthetics, social life, economics, or philosophy.

Following is an outline of findings in the empirical literature that describes the antecedents and consequents of collectivism, as characterized by Triandis and Gelfand (2012).

Antecedents

Homogeneity of the Collective and the Culture

One antecedent of collectivism is the homogeneity of the collective. The more homogeneity the more collectivism. By contrast when members of the collective differ on their attitudes and values or do not agree concerning what are the group's norms of behavior, it is left up to the individual to decide which normative system to follow, and thus there is individualism.

Interdependence Imposed by the Situation

Collectivism is higher when members of the collective are interdependent, for example when they engage in activities that must be coordinated and when what one does affects the success of others, or where cooperation is essential for success. When the goal is to execute large projects such as irrigation canals, or defensive walls, collectivism is more likely. In societies where people are financially interdependent, collectivism is high.

Population Density

In dense social environments many rules develop that are designed to reduce conflict and ensure the smooth functioning of the group. People make sure that the rules are observed. When group norms are more important than attitudes as determinants of social behavior, collectivism is high. Urban environments often include members of different groups, and individuals can decide for themselves whether to observe the norms of one or another group, thus they become idiocentric. On the other hand, an urban setting may have neighborhoods of culturally homogeneous individuals, which increases the collectivism of that group.

Social Stability

When the collective is stable, it is more likely to develop agreements about norms, and to make sure that the norms are observed. By contrast, individuals who have migrated from their societies or have experienced social mobility are more likely to be idiocentric. When social change is slow, the norms can be observed more reliably than when social change is rapid. There is evidence that the older members of all societies are more allocentric than the younger members.

Low Economic Status

Since the poor have fewer choices in life, and tend to do what norms specify, they tend to be more conforming to social norms than members of the upper classes. When resources are limited, one often depends on group members for assistance, especially in emergencies. These factors increase collectivism. On the other hand, those in positions of leadership tend to be idiocentric.

One Large Ingroup Rather than Many Ingroups

Those who only have one ingroup can channel all their energy into that group. Also, they cannot afford to develop poor relationships with members of that group, so they are more likely to observe its norms. Those who have many ingroups have superficial relationships with most of them, and if they do not have good relationships with one of these ingroups they drop it and spend more of their energy with some other ingroup. Intense involvement in relatively large ingroups (extended family, religious, or national ingroup) is more common among collectivists than individualists. Intensive involvement in individualist cultures is usually limited to first-degree family members.

Low Exposure to Other Cultures

People who only know one culture are unlikely to have more than one set of norms for social behavior. They tend to be maximally ethnocentric, authoritarian, and submissive to ingroup authorities. Those who are more educated, traveled, and have lived with more than one cultural group develop idiocentric tendencies.

Salient Common Fate

Common fate with members of the ingroup (e.g., the ingroup is under attack) increases collectivism. Time pressure for decisions has similar consequences. When there is time pressure an ingroup authority must make quick decisions that do not allow time for discussion and that places most members of the ingroup in a condition of common fate, as well as requiring conformity to these decisions.

Collective Mobility Is Advantageous

If individual upward social mobility is not possible, then collective mobility may be used. Thus, individuals invest their

energy in promoting the status of their ingroup. For example, people who do not get promoted on their own might join a union and invest their energy in promoting the union.

Large Families

In large families it is not practical to allow each child to follow idiosyncratic schedules, or have much privacy. Many rules are enforced, and that creates collectivism.

Strict Religious Upbringing

Most religions use a large number of norms that are reliably observed. That increases collectivism.

Little Exposure to Modern Mass Media

Analyses of the content of television programs made in the USA show that the themes used are often highly individualistic (emphasis on pleasure, doing what the individual wishes to do even if that is inconsistent with the wishes of groups or authorities). Countries where people have little exposure to such mass media tend to be more collectivist.

Consequences

Socialization

In collectivist societies, children are usually socialized to be obedient, reliable, to follow traditions, do their duties, sacrifice for the ingroup, and be conforming. In contrast, self-reliance, self-control, and independence are usually emphasized in individualist societies (Berry, 1979; Bond and Smith, 1996),

Low Well-Being

While members of all cultures are satisfied with their life (Tov and Diener, 2007), members of collectivist cultures are less satisfied than members of individualist cultures. Well-being tends to be correlated with individualism (Diener et al., 1995). Even when controlling statistically for income, this relationship persists.

Consequences for Cognition, Emotion, and Motivation

Markus and Kitayama (1991) have reviewed an extensive literature that shows that members of collectivist cultures differ from members of individualist cultures in their cognition, emotion, and motivation.

Social Behavior

Collectivists are extremely concerned with saving their face, and even attempt to save the face of the persons with whom they are interacting. Preserving harmony within the ingroup and being pleasant in relationships with ingroup members are often important values. On the other hand, collectivists do not care much about their relationships with outgroups. They usually behave quite differently toward ingroup and outgroup members, showing sacrifice and extreme cooperation with ingroup members, and suspicion and hostility toward outgroup members.

Receive Much Social Support if They Conform

Allocentrics report that they receive more social support and a better quality of social support than idiocentrics. However, those who do not conform to ingroup norms are rejected, and may even be killed (Triandis, 1995).

Have Poor Skills in Entering New Groups

Members of collectivist cultures do not have good skills for entering new groups because they are not socialized to do this. They are comfortable as members of their ingroups, thus they do not need to enter other groups. On the other hand they have more intimate relationships with those whom they interact with than idiocentrics who tend to have superficial relationships (e.g., cocktail parties).

Are Easy to Mobilize for Confrontations with Outgroups

When ingroups are in conflict it is easier to arouse members of collectivist cultures to fight for the ingroup than it is to do so with members of individualist cultures.

Describe the Self by Using Roles, Groups

When asked to complete 20 statements that begin with 'I am …,' members of collectivist cultures provide sentence completions that have more social content (I am a brother, I am a member of the communist party) than members of individualist cultures.

Attributions

Allocentrics make external attributions in explaining events (e.g., norms, group pressure), while idiocentrics show the opposite pattern (e.g., personality, attitudes). Thus, idiocentrics make the fundamental attribution error (seeing internal more often than external causes for the behavior of other people, while seeing external causes more often than internal causes for themselves) more frequently than allocentrics. Also, allocentrics attribute their successes to the help they have received from others and their failures to personal shortcomings (e.g., I did not try hard enough).

Have the Ideal of Fitting-In Rather than Shining

Allocentrics prefer to fit in and be like most others in their ingroup rather than shine and sticking out. Idiocentrics tend to be high in self-enhancement (report that they are better than most other people on most desirable attributes). Allocentrics tend to be modest when they compare themselves to others.

Show Little Social Loafing

Allocentrics show little evidence of social loafing (the tendency to produce less when they work in a group than when working alone, if their output is not identifiable). They

usually produce as much as possible when they work with ingroup members, but they show social loafing if their coworkers are outgroup members.

Within the Ingroup Distribute Resources Equally or According to Need

When interacting with ingroup members, members of collectivist cultures tend to distribute resources equally or according to need. When interacting with outgroup members, however, they use the equity principle (to each according to contribution).

Recreation Occurs in Groups

Members of collectivist cultures seek recreation in groups rather than alone to a greater extent than members of individualist cultures (e.g., bowling rather than skiing).

Communication

During interpersonal communication, members of collectivist cultures rely on the *context* (such as distance between and position of bodies, eye contact, gestures, tone of voice) more than on the *content* of communications. For example, rather than saying 'no' they may serve incongruous foods, to put across their negative message without causing the other person to lose face. When they describe a person they are likely to use context, e.g., 'he is intelligent in the market place,' rather than decontextualized statements such as 'he is intelligent.' Silence is used more than in individualist cultures. Compliments are not used as frequently as in individualist cultures. The languages of collectivist cultures do not require the use of 'I.' Collectivists use more action verbs (e.g., he asked for help) rather than state verbs (e.g., he is helpful), which suggests that they use communications that make greater use of context, are more concrete, and place less emphasis on internal attributes of the person.

Conflict Resolution

Members of collectivist cultures avoid conflict with ingroup members, and in the case of disagreement prefer silence to argument. They prefer mediation to confrontation.

Conformity

Members of collectivist cultures show more conformity in experiments that measure conformity.

Emotions

Members of collectivist cultures get angry when something unpleasant happens to ingroup members more often than when something unpleasant happens to themselves. They do not express negative emotions as often as members of individualist cultures. Collectivists often have emotions that reflect relationships (e.g., sympathy), while individualists often express emotions that reflect independence (e.g., pride).

Apologize More for Transgressions of the Ingroup

Members of collectivist cultures apologize more when an ingroup member commits a crime than is common in individualist cultures.

Globalization and Collectivism

In the process of globalization, is collectivism to be avoided and individualism to be promoted? This issue is especially relevant as societies become more affluent, because they tend to acquire some of the attributes of the West, including individualism. The group is rejected, and the individual becomes the center of social change. People in cities, in small apartments that do not have room for extended families, thus drift toward individualism.

Is 'economic development' necessarily associated with more individualism and less collectivism? My view is that the problem is much more complex than just stated. First, one can be both modern (use computers and fax machines) and collectivist. Second, societies are complex, i.e., they have many aspects. Some aspects might change and become more Western, while most aspects may stay the way they were. In general superficial attributes, dress, public behavior, and economic life might change while fundamental values may not.

In any case, for collectivist societies, one might ask: is it desirable to 'promote' individualism, or better to stay with collectivism? As is the case with most complex issues, the answer is 'it depends.' A major problem can be the extremity of collectivism and individualism. Extreme collectivism is stifling. One becomes a tool manipulated by others, unable to reach personal goals. Extreme individualism is isolating, and leads to ego-centered narcissism. Furthermore, extremely individualistic societies are often extremely competitive, and that results in remarkably high levels of stress. Escapes from stress may include drug abuse.

It is possible to list both positive and negative factors associated with each cultural pattern. In the case of individualism we find affluence, self-determination, and self-actualization. These factors are associated with feeling good about oneself, and being satisfied with life and being happy. Also, in individualist cultures there is an emphasis on individual rights, and people are expected to shape the direction of societal change to fit their personal needs.

On the other hand, Naroll (1983) has assembled much empirical information suggesting that the weak interpersonal bonds that are associated with individualism result in higher rates of civil disturbance, riots, murder, delinquency, theft and fraud, drug and alcohol abuse, suicide, brawling, wife beating, child battering, and mental illness. The competition found in individualist cultures often results in some segments of the society remaining economically behind and becoming especially susceptible to social pathologies.

By contrast, collectivism is associated with social controls, including extreme punishment for crimes, prompt punishment, and active gossip. Social control is also achieved through emotional closeness, social support, appeals to memorable myths, and a plausible ideology that supports the ingroup's

norms. People feel embedded in the social system, so they are less likely to try to change it, to commit crimes or suicide, to steal from the ingroup, or use drugs that isolate them from it. One of the best predictors of drug abuse is the combination of high pressure for achievement with low social support, a combination often found in individualist cultures.

On the negative side, collectivism is often found in societies where groups assume that the individual is relatively unimportant and must do what is best for the group. This is especially significant when the group is the state. People are expected to be 'patriotic,' and sacrifice themselves for the good of the state. However, very often, what is good for the state is in fact only good for those in power, who frequently take advantage of the masses to further their personal goals. As we have seen, leaders in all cultures are idiocentric, and the history of the world offers too many examples where they order their followers to do what is good for the leader rather than what is good for the followers. Also, collectivism makes it easier to convince the ingroup to fight outgroups, and wars are more frequent between collectivist countries than between individualist cultures. In a world with nuclear weapons, there may be much to be said in favor of reduced collectivism.

Note also that while the social pathology associated with individualism is formidable, it does not affect most individuals in a society. Pathology by definition is found among a small minority in any society. Thus, the majority can enjoy the benefits of affluence without the negative consequences of individualism.

In short, an evaluation of the desirability of collectivism or individualism depends on what criteria we wish to maximize. If we wish to emphasize the creativity that individualism allows – which often results in more affluence, the freedom and self-actualization of individuals, democratic processes, and the independence of individuals from the social pressures of groups – we may wish to see globalization leading to more individualism. But if we wish to emphasize family values and the values of the ingroup, we may resist the weakening of collectivism associated with affluence. These values include religious beliefs, the social support that one can get from the ingroup in moments of crisis, and the security, both material and emotional, that the ingroup can provide.

In addition to the above considerations, there are issues of individual differences. For those who are intelligent, educated, easily changed, and adaptable, an individualistic society can offer a great deal. Creativity requires freedom to pursue different courses of action and in a society where one is supposed to consult others, and act according to well-established customs, creativity is not likely to flourish. On the other hand, for those who value especially family life, harmony, security, and social stability, a collectivist society may be optimal.

Abstract

Randall Collins is a leading social theorist in the late-twentieth/early twentieth century. Born into a diplomatic family, he soon gained an equanimous view of, and an interest in both global conflict and the dynamics of social appearances. After studying with Parsons, Blumer, and Goffman, he made a double breakthrough simultaneously reshaping conflict sociology, and detecting credentialism. He has developed and integrated a microsociology of interaction ritual chains, a macrohistorical sociology focused on market and geopolitics effects on state dynamics, and a mesosociology of networks – illustrated by his overarching historical-sociology study of philosophers' networks. Presently he investigates violence at all three levels.

Introduction

Randall Collins (Knoxville, Tennessee, 1941) is one of the most insightful, innovative, and prolific social theorists in sociology at the beginning of the twenty-first century. Together with more than 300 papers delivered in Universities, academic conferences, and professional meetings all over the world, and almost 200 articles and book chapters, he is author of 13 academic books (plus a novel), and co-author, editor, or co-editor of another 5, with 14 of them translated to different European and Asian languages. He has contributed fundamentally to several research fields, particularly conflict theory, the sociology of education, the sociology of the intellectuals, microsociology, the macrohistorical sociology of political, economic, and cultural change, and the sociology of violence. His constructivist view of social theory as a logically coherent body of ideas, which explains the variations of social phenomena in terms of general principles inferred from comparisons among rigorously obtained empirical data: his idea of the epistemic integration of the micro- and macrosocial realms through the mesolevel of networks; his theory of interaction ritual chains; his geostrategic view of world history; his notion of democracy (defined as collegial government plus the extent of franchise); and concepts as credential inflation, rapid-discovery science, emotional energy, stratified attention space, confrontational tension/fear or forward panic have significantly enriched contemporary social theory.

Early Years

Collins' family background, early life experiences, and university years deeply influenced his subsequent intellectual and research career. His maternal grandfather, a German immigrant in the 1890s, was a noncommissioned officer in the US army for 30 years. His father, originally a professor of German before joining the US Army intelligence, and then the State Department, was trained in Russian during World War II and sent to Berlin in 1946, and later, to Moscow (1949–51). As a diplomat there, he was in the political section of the embassy – his mother performing heavy duties as a 'diplomatic hostess.' That is why some of Collins' first nonfamily memories are about a bombed-out city, unexploded shells, unburied dead soldiers' bodies, and Russian children throwing stones against their family dacha after the outbreak of the Korean War. As a child, he reckoned those as normal facts of his environment, not as fearful or cruel ones. That gave him soon a clear sense of violence, or at least conflict as a common feature of life.

Similarly, witnessing the military often scarce interest in fighting – their main interest is maintaining the routine–, his mother's recurrent need to retire temporally to a hotel to rest and read novels (because of what he would later call 'interaction fatigue'), and his father 'decoding' activities (he became what was then called a kremlinologist), and by his sheer acceptance of all of it as familiar facts, and not necessarily morally labeling conflict as disgrace or strategic behavior as hypocrisy, prepared him for the functionalist view of conflict as a sometimes change-triggering but also sometimes homeostatic event, and for the Goffmanian idea of a front stage/backstage partition of social life. Although his father rarely spoke out his own personal opinions, his performance in his official position during a cold war marked by the arms race, and the possibility of a nuclear war gave Collins a strong consciousness of international and military actions, and a firm affinity with the peace movement, that would lay the foundations of his life-long interest in, and his geostrategic understanding of macrosociology.

A University Student in the Sixties: Harvard, Stanford, Berkeley

After living his earlier years mostly overseas, his family sent him to a New England preparatory school where he was trained to attend Harvard College – and his contact with upper-class students there made him for the first time acutely aware of class differences. As an undergraduate there Collins briefly tried studies in engineering, mathematics, and literature, before opting for social relations – a blend of sociology, social psychology, and anthropology. He soon felt attracted by research, and he started investigating on Piaget's ideas looking for a way to synthesize them with Freudian theories – then strongly connected with the fashionable philosophy of existentialism through Sartre's attempts to build an existential psychology by integrating and expanding out some of Freud (although Camus' *The Rebel* was personally a more inspiring reading). At the same time he shared the recent and growing

interest in the culturally and historically oriented work of Luria, Vygostki, and their circle – which he felt had strong parallels with the sociological view on language and thinking – as introduced to Harvard students by cognitive, language, and educational psychologist Jerome Bruner.

Collins also attended Talcott Parsons classes at a time when he was brilliantly lecturing about Durkheim and Weber's theories of religion, and also trying to integrate Freudianism within his scheme of the social system as the set of mechanisms of the personality system that would induce the individual to interiorize the cultural system, thus providing the basis for the structuring of society – an early attempt at what Collins would later call 'micro-macro integration.' Another Harvard teacher was then George Homans, who since the 1950s was stating, against Parsons, that society is an epiphenomenon of individual actions (at their best chosen by rational calculus) and that sociological explanation can be reduced to behaviorist psychology – ideas that would form the theoretical nucleus of Exchange Theory and then Rational Choice Theory. Later in his career Collins would question the empirical base and the explanatory scope of these paradigms but then the relevance for him of this coexistence in the same university department of such diametrically opposed views was that it gave him a taste of how science flourish in – actually, thanks to – a milieu of theoretical contest and intellectual rivalry, a key concept in his theory of intellectual networks.

Having obtained a BA in psychology in 1963 Collins moved to Stanford University, where he took an MA in psychology that he expected would correct what he felt as Harvard's somewhat narrow theoretical emphasis through Stanford's insistence on laboratory and experimental type studies – as, among others, Leon Festinger, who had recently formulated his theories on social comparison and cognitive dissonance, was promoting there. Nonetheless, Collins had already decided to shift to sociology. Thus, he moved to Berkeley where he would be awarded an MA (1965) and a PhD (1969) in sociology. Berkeley Sociology Department was then intensely attractive because it was a crossroads of paradigms and a hub of professors of fascinating scientific height and engaging personal enthusiasm – what Collins would later call 'energy stars': Joseph Ben-David, Reinhard Bendix, Herbert Blumer, Erving Goffman, Seymour Martin Lipset, or Neil Smelser, among others.

Collins had co-authored just one psychology article (published in *Nature*, though) before becoming Ben-David's research assistant. Usually identified as a member of Robert K. Merton functionalist school, this sociologist of science and expert on the history of university systems and their transformations was at that time visiting Professor in Berkeley, and he was doing research for a book on the world history of the role of scientist. With him Collins did a network analysis of the origins of experimental psychology (mainly in nineteenth-century Germany), and derivatively grasped that the philosophers who led the Idealist movement (Kant, Fichte, Hegel, Schelling…) were connected in a network, and were involved in the struggle to reform their received university system into a system based on the research university. This investigation, published in two articles co-authored with Ben-David, showed him that both the networks of vertical relationships from masters to pupils, and horizontal among these, in intellectual fields, and the material-organizational base of intellectual work strongly affect intellectual production. This was the first seed of what would eventually become *The Sociology of Philosophies*, a book on which Collins would be working the following three decades. His association with Ben-David also reinforced his interest (already nurtured by Parsons) in wide historical comparisons as a means to uncover macropatterns – something decisive for his following endeavor, in collaboration with Reinhard Bendix.

Bendix had exiled in his early twenties from Nazi Germany and attended the University of Chicago, where he took a BA and a PhD in sociology. He first got acknowledged for his work on social mobility with ex-Marxist Seymour Lipset, and shortly after he set a strong Weberian position with his book *Max Weber: An Intellectual Portrait* (1960). He enrolled Collins into a research project that led to the publication of a co-edited reader: *State and Society* (1968). Collins' contribution to this issue, "A Comparative Approach to Political Sociology," where he explicitly adopted an anti-Parsonian stance (then a brave move), became his first influential text. Both Parsons and Bendix followed Weber, the former emphasizing his cultural side, the latter his political side; and perhaps it was the accident of having studied with both of them that enabled Collins to devise a more multidimensional view, one that took into account both stratification and conflict as crucial social phenomena.

In Collins' view, Weber had focused as no other sociologist on the state, and the collective struggles to monopolize the organization of force and the means of generating legitimacy, as key social phenomena. In addition, he had asserted an enduring tenet of sociology: that the three basic dimensions of human social structures are those concerned with material/economic things (class), communities of cultural membership (status), and organizational social control (power: including both politics and violence). Defying both functionalist and Marxian approaches to political history, Collins multidimensional perspective offered a more balanced analysis of those dimensions, and their mutual interactions. His view was later shared and developed by those scholars that created the military-fiscal theory of the upcoming and expansion of the modern state, its most important revolutions and other geopolitical dynamics of historical change, and also the field of social movements studies.

At the other wing of the antifunctionalist front were those professors whose common denominator was their interest in the close analysis of everyday life. In Berkeley, their most respected and authoritative figures was Herbert Blumer, then finishing his classic book *Symbolic Interactionism: Perspective and Method* (1969). Apparently a strong individualist (already famous for his attacks on statistics and 'the variable' – because variables actually do nothing – and for asking his students: "Where is social class? Where do you see it?"), and an old-fashioned gentleman who neither took part nor encouraged student mobilizations and demonstrations, he was nonetheless one of the few prominent members of the university staff who supported their movement and even gave them a theoretical rationale for it. An inspiring teacher, he was widely admired because in the theory course required for all graduate students that he taught he set up a theoretical link with campus-based civil rights, antiwar, and prouniversity reform campaigns,

giving them intellectual tools to understand what was happening: he stressed that the social order is always the result of all the groups of people who mobilize themselves to define what social institutions are; that an organization exists only to the extent that people act it out – when they stop interpreting it as existing it stops existing; or that power is a social construct and it can change very rapidly if a collectively sustainable reinterpretation occurs.

Blumer had been G.H. Mead's teaching assistant and took over his class when Mead died in 1933. He deeply identified himself with Mead and he often lectured as if he was just reporting Mead's ideas, but he actually created much of symbolic interactionism: he thought of its name, designed empirical research strategies for it, and refined its concepts, substantially emphasizing actors' definition of their situation, and strongly stressing the possibility of reinterpreting the situation, thus allowing for the relative volatility to social life. These are the roots of Collins' radical microsociology, and of his ambition to find macrosocial dynamics in microinteractional situations; to show how, through organizational and/or communicational networks, both poles of social dynamics influence each other, and their middle ground.

Nevertheless, the star of interaction studies was Erving Goffman. Twenty years younger than Blumer and then at the height of its theoretical creativity, Goffman's lectures were always crowded, not because he was a charismatic personality but because of the quiet but extreme intensity with which he expounded his empirical observations and his concepts: front stage and backstage, face work, total institutions, interaction rituals, frames, etc. They were an eye-opener experience: almost everything people were doing was socially constructed; it was all social rituals, and they all operated (more or less unconsciously) to enact a certain kind of social order – which, most students thought (Collins among them), just the same could also be torn down. Personally, though, Goffman was much more difficult to get along with. He did not allow many people to be personally close to him, and he often played 'one-upmanship' on other people – trying to embarrass them while maintaining one's own demeanor. Collins thus decided to keep politely distant from him and confine their connections to intellectual matters, where they shared more affinities.

Goffman had also started as a Freudian, but he gathered that conscious and unconscious processes could be empirically better investigated by looking at them anywhere in the everyday life of children and adults – if the researcher had enough mental discipline and observational insight to grasp the details of people's behavior, and sufficient acumen to interpret them theoretically. Feeling himself apt for the task, Collins changed allegiances from Freudianism to micro-interaction analysis. Also, Goffman disliked to be tagged a symbolic interactionist as, having studied in Chicago, he often was; but, because of his knowledge of Parsons, Collins was able to recognize his Durkheimian side, thus interpreting his theory in the way he preferred – although he said Collins was turning it into Marxism because he focused on how social rituals change historically, and how they apply to conflict and violence, among other themes alien to Goffman interests.

Eventually, their relationship became strained. Goffman upheld that society exists and is primary and, citing Durkheim in his support, also that society constructs the individual self and makes it a sacred object – who returns the favor, in its own benefit, by itself frequently giving ritual respect to other selves, which reciprocally uphold the former one. Collins was deeply skeptic of this explanatory undermechanism, and when, partly to test the scope of this assumption, he once asked Goffman what he thought would be a microsociology of the intellectual world, Goffman brushed the question aside with a characteristically sarcastic remark. Finally, Collins was perhaps the first theorist to attach to the micro-macro dichotomy a new sociological sense in his article "The micro-foundations of macro-sociology" (1981a), in which, from a nonreductionist stance, he asserted the theoretical primacy of microsituations. Possibly in response to it, Goffman (1983: 7) stated in his Presidential Address to the *American Association of Sociology* that "(some) argue reductively that all macro-sociological features of society, along with society itself, are an intermittently existing composite of what can be traced back to the reality of encounters, a question of aggregating and extrapolating interactional effects. (…) I find these claims uncongenial," which may be read as an utter rejection of Collins' claim.

Political differences added to their increasing lack of mutual rapport. Absorbed in his research, Goffman stayed out of politics – not like young Collins. Soon after getting to Berkeley, Collins had joined a fairly idealistic civil rights group and participated in nonviolent sit-in demonstrations for the Free Speech Movement, and against racial discrimination and the Vietnam War. Some of the group members were Marxists: Stalinists, Maoists, and Trotskyites – and Collins associated with the latter. Nonetheless, as the antiwar movement actions became soon more violent many people left what was actually a political movement of intellectuals (most members were graduate students) and drifted toward its spreading into popular culture through popular musicians and the drug culture: they became more interested in the hippie counter-culture revolution, the quasi-religious psychedelic drugs movement, the encounter group psychotherapy movement, Eastern mystical religious movements, transcendental meditation, etc., all of it dressed up with rock music, and an erotic/sexual revolution. Collins became briefly a hippy, went to group therapy, and learned quite a lot about Buddhism studying with Tibetan and Japanese monks – which gave him a basis for his later sociological research on Eastern philosophers for *The Sociology of Philosophies*.

An Academic Career: Early Breakthroughs and Collins' Discontent

After reading his PhD dissertation in 1969 Collins got appointed as an assistant professor, then associate professor by the University of California–San Diego, where he stayed till 1977. There he met and became friend of Visiting Professor Alvin W. Gouldner. After being simultaneously invited by an American and a Dutch publisher respectively to start a theory-oriented journal, both agreed to combine the two enterprises, asked Pierre Bourdieu to join them, and founded *Theory and Society*. In 1979 he would be also founding editor of American Sociological Association journal *Sociological Theory*. It was also an extremely fruitful writing time: the three books Collins

published while being in San Diego gained him an enduring reputation as an insightful and path-breaking scholar.

Co-authored with Michael Makowsky, *The Discovery of Society* (1972, eighth edition 2009), now a classic introductory text to the history of sociology and to sociological theory, appeared first. Written as series of sociobiographically well contextualized intellectual and conceptual portraits of those nineteenth- and twentieth-century thinkers most significant for social thought – from first and second generation founding fathers (Comte, Marx, Tocqueville, Nietzsche, Durkheim, Weber, Pareto, Freud, Mead), through the age of sociology academic institutionalization (the Chicago School, Parsons, Goffman) to a selection of present theorists mainly focused on macro- and micro-investigations about conflict (Bourdieu, Skocpol, Wallerstein, Elijah Anderson, Donald Black), it included two chapters on evolutionism and racism, and on the emergence of African-American sociology – matters rarely treated by textbooks.

Then came *Conflict Sociology* (1975; updated edition, with Stephen K. Sanderson, 2010), that gestalt-shifted the perception of numerous authors and studies, formerly considered to be heterogeneous, into a new understanding that they constituted a coherent research field – which became named after this title. Writing from a coherence theory of truth, opposed to positivist empiricism, to dispel the prejudice that sociology was not a cumulative science, Collins arrayed it in terms of basic propositions, their logical relationships, and the phenomena – empirically documented through rigorous historical, ethnographic, and observational evidence – which they explained. It covered several areas: state development and dynamics, markets evolution, stratification and social mobility, class struggles, and deference and demeanor, among others. He wanted to show that an integrated conflict theory that synthesized the best insights of the Marxian, Weberian, and (through Goffman) Durkheimian traditions could explain a wider range of sociological issues than other views. This approach was later vindicated, since the fields of social movements (Tilly, McAdam, Tarrow, etc.) and historical sociology of the state (Skocpol, Tilly, Goldstone, Mann, etc.) set out and developed successfully precisely from a similar Weberian perspective. It is also congruent with a world-system view. Nonetheless at the time the book's viewpoint failed in a disciplinary sense because in the highly conflicting early 1970s sociologists were not for synergies and synthesis, but polarizing into several varieties of factionalized Marxism, hard-line well-funded positivism armed with more advanced statistics and bigger data sets, radical social constructivism as ethnomethodology, and post-modernism. After this setback Collins would never try again such a direct strategic syncretistic move – in the future he would rather work from both macro- and micropoles toward each other simultaneously.

Lastly, in 1979a, came out *The Credential Society: A Historical Sociology of Education and Stratification*, which basically held that just expanding contemporary educational system could never produce social equality. Instead of that, its inflationary dynamic would only cause longer pursuits of more and higher degrees in the often misguided hope that they would help to achieve better jobs and higher class positions, and that this demand would fuel public and private offers – only checked eventually by its increasing costs, and decreasing returns. Facts have essentially borne out Collins' thesis globally for more than 30 years. Furthermore, Collins' convictions guided his personal life: he had then a revolutionary orientation and believed the bases of stratification should be somehow overthrown, and so while writing *The Credential Society* he came to feel that it would be hypocritical to keep working in the credential-creating academic system. Consequently, he quit his academic post in 1977 and worked in commercial writing for a year before accepting a professorship in the University of Virginia, which he held up to 1982. Then he quit again and worked as a professional writer for another 3 years.

(Incidentally, Collins also published in 1979b his novel *The Case of the Philosophers' Ring*, written in 3 weeks after he bet against a friend that he could write a Sherlock Holmes story in that time using a well-tried formula: 'Holmes meets…' – here famous 1900s cultural figures: Wittgenstein, Russell, Keynes, Ramanujan, Virginia Woolf, and many others, as he took advantage of his work on intellectual networks.)

During those days of independent scholarship alternated with resident and visiting professorships, Collins made his living mainly by writing textbooks – which admittedly makes profit of the academic system too; as a moral compensation, he tried to raise his works at this generalist-synthesizer's trade above the common level. And he worked hard: 5 books in 5 years. The most theoretically noteworthy of them is *Sociological Insight* (1982, second edition 1992), where he head-on criticized rational action theory. Collins stated that in any socially meaningful context the key mechanisms of human choice rather more frequently than the cognitive mechanisms emphasized by the utilitarian tradition involve decision habits and practices developed and learned in interaction rituals involving emotions, a microinteractional focus and mutual entrainment. To show the explanatory fruitfulness of his ritual–interactional approach Collins applied it there to several macroscale phenomena: religion, power, crime, sex/love, and even artificial intelligence. Another major scholarly successful book was *Sociology of Marriage and Family: Gender, Love and Property* (1985b, fifth edition 2000; from the third on co-authored with Scott Coltrane), an extensive, historically informed, and conflict-sensitive handbook which ranges from the geopolitical and economic conditionings of kinship-family structures through love and marriage markets (influenced also by social class, racial, ethnic, and other social and cultural variables – such as the rise of feminism) to intimate issues such as erotic ties, contraception, childbearing, marital cohabitation, violence, etc.

The other three books dwelled on the history of sociological theory. In 1981b he published *Sociology since Mid-Century*, a collection of papers and reviews on some of his constant themes (the empirical support for conflict theory; geopolitics, social change, state power, and revolution; symbolic and physical violence; schooling in the USA) together with sharp analysis and balanced criticism of several contemporary social thinkers (Blau, Goffman, Gouldner, Levi-Strauss, Merton, Touraine, Wallerstein, etc.) In 1985a *Three Sociological Traditions* (and its accompanying edited reader) followed, a bold comparative assessment of Marx–Weber–Coser conflict-oriented viewpoint, the ritual solidarity/functionalist paradigm of Durkheim–Parsons–Goffman, and the interactionist view of Mead–Blumer–Garfinkel – expanded later with rational choice

theory as *Four Sociological Traditions* in 1994. Finally his brief *Max Weber: A Skeleton Key* (1985c) appeared in a collection of short biographies of classical social theorists.

An Academic Career: An Integrative and Innovative Sociological Theory

In 1985 Collins returned to the University as Professor of Sociology in California–Riverside, where he spent the next 12 years – but he did not work on credentialism again for decades. There he began to fully develop his overarching view of Sociology. If *Sociological Insight* had stated his sophisticated Durkheimian position regarding microsociology, *Weberian Sociological Theory* (1986) did the same for macro- and meso-sociology from a Weberian perspective. Collins showed that Weber's late work, based on massive historical comparisons, offered theories of the origin of capitalism (in rationalizing practices of medieval Christian and Buddhist monasteries), and of the development of the state (as a rationalizing by-product of a world-system model of geopolitics) that had hitherto been utterly neglected. More importantly, Collins showed how to apply the more fruitful lines of Weber's approach – state/market macrolevel dynamics – to the analysis of cultural issues such as dissidence (whether religious heresy or intellectual alienation), or the evolution of family structures and women's social status. This book also included a chapter devoted to the prognosis of the future decline and eventual demise of the URSS – originally formulated in a 1978 article, and that most people found conspicuously preposterous then but which would soon enhance Collins academic fame perhaps more than any other of his former contributions.

Theoretical Sociology (1988), perhaps Collins' most ambitious book to that date, was simultaneously a textbook on sociological theory and an attempt to assess what valid theoretical, and most importantly empirical knowledge there was in several theoretical schools: at the macrolevel evolutionism, functionalism/system theories, Marxism and its kin, and conflict theory; Mead–Blumer's symbolic interactionism, Homans-Blau's exchange theory, and Goffman's interaction rituals at the microlevel; and what was the main innovation of the book, a section on mesolevel theories, including chapters on the micro–macro link, network theories, and organization theories – conceiving organizations as network-structures operating at that level, whose mechanisms shape the conditioning circumstances of their composing microinteractions with different kinds of task and communication problems. On the whole, the book was not very successful, mainly because of its criticism of fashionable theories such as postmodernism.

An Academic Career: An Overarching View and Violence Studies

In 1997 Collins became and has been since the Dorothy Swaine Thomas Professor in Sociology at the University of Pennsylvania, and it has been there where his *oeuvre*, i.e., his attempt to build a comprehensive sociological theory has flourished and finally earned him world recognition. In 1998, culminating more than 30 years of research, he published *The Sociology of Philosophies*, a full analysis of more than two millennia of Eurasian philosophical networks. This massive historical comparative exercise in mesosociology yielded impressive discoveries such as the 'law' of the small number of philosophical positions (often six) viable simultaneously in an intellectual attention space; the basis of 'rapid-discovery science' in genealogies of laboratory equipment connected by networks of persons who modify and recombine them into equipment that produces a stream of new phenomena to study; the concept of ideas as social coalitions of thoughts guided by their prospective relevance in valued intellectual networks; the pragmatic view of intellectual greatness as sociocognitive usefulness for next generations of thinkers; or the dependence of creativity on a thinker's network position, which determines the cooperative-competitive rituals and consequently the emotionally charged ideas she/he has access to, and the emotional energy she/he gets there to combine them in new potentially successful ways, etc.

In 1999 it was the time of *Macro-History*, a collection of essays aligned with the most successful modern historical sociology, where Collins presents a theory of market dynamics across history including early kinship structures based on marriage markets, ancient military states based on conquest of slaves, religious corporate capitalism in medieval Christianity and Buddhism, and modern capitalism with its expansion and crises. Collins also shows how wide historical comparisons can lead to solid generalizations on, for instance, the variations of ethnic dominance within states, the extent and health of democracy, or the chances of success of social revolutions. Finally, after co-editing with Mauro Guillén and others *The New Economic Sociology* (2002), and as if rounding off a trilogy devoted to the three levels of social dynamics, Collins published *Interaction Ritual Chains* (2004), a work which presented a general theory of social rituals as a general purpose tool to understand microsituations, based on a full analysis of the functioning of ritual interaction situations as mechanism for building collective identity and solidarity.

Developing and combining insights from both the tradition of minute conversational analysis (Sacks, Schegloff, Sudnow) and the sociology of emotions (Jack Barbalet, Arlie Hochschild, Jonathan Turner, Thomas Scheff), Collins explained interaction rituals' intellectual, moral, and behavioral efficacy by their build up or draining down of a measurable and quantifiable individual variable he calls emotional energy, a distinctive social emotion subjectively felt as strength, self-confidence, and thrust to take the initiative and participate in social action. Emotional energy is, together with emotionally charged symbols of one's group, a feeling of collective belonging and a moral stance on behalf of that group, the ordinary fruit of successful rituals. A market-like dynamics where agents compete in order to participate in the best rituals their material/personal/cultural capital gives them access to, and to foster those they find most rewarding, sustains the network of ritual occasions that make up the interactional structure of a culture. Collins applies this theory to the evolution of sex/love and to tobacco rituals, to historical variations in modern Western elites rituals of power/deference, to economic/social/status-fame stratification at large, and to the social construction of the innermost parts of the individual self: the very process of thinking of an individual and her/his personality type – even

the seemly less social one, the introvert, as shown in his historical diversity.

Recently Collins has embarked in what will be another series, now on social violence. Going beyond the analytical approach of conflict theory, he studies the actual dynamics of fighting at microlevel – where shared focus of attention and a common (negative) emotion generates tension/fear instead of rapport – and its effects at every other social scale. Its first installment was *Violence: A Micro-Sociological Theory* (2008), an investigation on actual moments of fighting and almost-fighting based on first-hand empirical data (eye-witness written testimony, real-life photos, and videos), which shows that humans tend to be averse to face-to-face violence and very incompetent when they resort to it. This would be a consequence of an evolution-developed innate and socialization-enhanced human propensity to collectively entrain in cooperative ritual behavior (conflict being a result of variously motivated failures of this dynamic). So, in potentially violent situations humans feel inhibiting tension-fear, and violence only proceeds when they find a way to overcome it – sometimes in severely destructive ways, as in forward-panics, when a group or an individual which have been under prolonged and serious threat suddenly get emotional dominance over its rival and charges viciously against her/him. History of violence is the history of techniques to train humans to be effective fighters. All this shows the falsity of current popular views of violence based in images and accounts edited by news media and stylized and glamorized by the entertainment industry.

The second book of this series deals with the time-dynamics of conflicts and its relation with collective dynamics of emotional motivation and domination. Collins (2012) Presidential Address to the American Sociological Association (he served as ASA president in 2011–12) may be considered as the book's forerunner article. The third book is expected to be devoted to recently developed forms of high-tech military violence, and the differences it purports for the emotional dynamics of war at all human levels.

Before that, though, he has co-authored with other four leading scholars from the field of macrohistory *Does Capitalism Has a Future?* (2013). Acknowledging that society at macroscale is too complex to allow for detailed predictions, they also believe that macrostructural conditions may be forecasted. Collins contribution offers a definite prognosis of dire straits for capitalism. Basically, he expects an underconsumption crisis as a consequence of a massive destruction of middle-class employment in the services sector due to the advance and world deployment of information technologies – which technology, spreading of markets, financing sector, government investment, or educational expansion will not be able to counterbalance. In order not to collapse, the world-system would evolve, through more or less peaceful or violent transitions, into a variety of central command economies whose governments, whether democratic, authoritarian, or something in between, would likely manage difficult redistributions of wealth by regulating or bypassing markets, endlessly balancing subsidiary capitalist and core central command – perhaps often socialist – features.

A closing remark: since 2010 Collins writes a blog (http://sociological-eye.blogspot.com.es/) where to date (September 2014) he has published 20 article-long essays on current social issues from the vantage point of microsociology (interaction rituals and the new electronic media, Mona Lisa's smile, USA immigration crisis), sociology of intellectual life (emotional energy and belief in free-will, Jesus' charisma, changing love plots y XXth narrative or film and the sexual revolution), political dynamics (recent tipping point revolutions, the hero of Tiananmen), sociological theory (sociologically significant quantities, ambiguity of material interests, network morphology dynamics, the intellectual descent of Goffman and Garfinkel), and sociology of violence (bullying, mass rampage killers, animal violence, organized crime, Alexander's and Napoleon's carriers). These texts illustrate once more the broad applicability and heuristic fruitfulness of Collins' three-tiered approach (Interaction-Ritual Theory, Network Theory, Macro-History Geopolitical (state-and-market) Theory) to comprehensively understand the courses and recourses of social life: how under macro-world-market/geopolitical and mesoorganizational constraints micro-meso-and-macro data get processed in microsituations process resulting in patterned recurrent individual and group behaviors that renew or change the micro-meso-and-macro structures and dynamics of cultures and societies. (This short biography is based in Maclean and Yocom (2000), Santoro (2012), and Waldstein (2007), in Randall Collins' books, articles, and blog posts, and in personal communication with him.)

Abstract

The article surveys aspects of the history of the anthropology of colonialism conceived as a story of successive contexts of questions in which the problem about colonialism for anthropology has been shaped and reshaped. It begins in the 1970s with the concern with the role of the discipline in the colonial/imperial project, and with the ethics/politics of its practitioners. These concerns with the effects of world politics are displaced in the 1980s by questions that turn on the problem of colonialist representation, the imbrication of power and discourse in the making of anthropological knowledge. In the context of the realignment of disciplines in the 1980s, there is also a reformulation of relation between anthropology and history. In the 1990s there is another shift, one away from an interest in textuality towards a concern with the relationship between colonialism and modernity. Here issues such as nationalism and the colonial state are reconceived. Finally, it is suggested that because the anthropology of colonialism has been oriented towards understanding the present as much as the past it has been importantly a *critical* enterprise. The article urges that to retain this critical purchase it has to more adequately specify the domain of contemporary *postcolonial* questions that theorizing colonialism is meant to illuminate.

The story of the relationship between colonialism and anthropology (or more specifically, of the anthropology of colonialism) is not the story of a neatly unfolding self-consciousness. It is, rather, the story of successive contexts of questions that have shaped the intellectual space in which the problem of colonialism for anthropology has been formulated and engaged.

Anthropological self-consciousness of colonialism, that is, of colonialism *as a distinctive problem for anthropological knowledge and anthropological practice*, begins roughly in the 1970s. In the early years of that decade two edited volumes appeared dealing with anthropology's relation to the social and political world of which it was a part. One came out of the tradition of US cultural anthropology, *Reinventing Anthropology* edited by Hymes (1972); and the other out of the tradition of British social anthropology, *Anthropology and the Colonial Encounter* edited by Asad (1973). Both collections perceived the discipline to be in serious crisis; and both were radical in the sense that they were explicitly concerned to subject that crisis to a fundamental self-scrutiny.

Hymes's volume urged that the social and political conditions in which anthropology had emerged as a professional academic discipline in the US at the turn of the twentieth century had, by the late 1960s, significantly altered. First, there was the overwhelming fact that with political decolonization there was a fundamental change in the conditions in which field- work could be conceived and undertaken. At the same time, the relation between the US government and the Third World (as the colonized or recently decolonized part of humanity came to be called from the 1950s) had given rise to troubling moral-political questions about the state of the anthropological enterprise. In particular, US involvement in attempted counter- insurgency in Latin America, and the role of anthropologists as cultural experts in the war in Indochina, served to pose the question of the relationship between 'objectivity' of ethnographic data and political interest in a very acute way (see Stocking, 1991). What place would anthropology have in raising fundamental questions about injustice and inequality in the world it inhabited, and what was its role in trying to transform that world? Was anthropology to be employed as an instrument of Western domination or as a means of liberation? Moreover, the publication of Malinowski's field diaries in 1967 and the revelation of his barely veiled racism further focussed attention on the ethics of the relation between ethnographer and informant.

In this context, the challenge *Reinventing Anthropology* sought to pose was whether the discipline would be able to transform – to *reinvent* – itself in a way that reflected the demands for political accountability, ethical concern, and critical social commitment on the part of anthropologists. Two strains in US anthropology inspired the volume's contributions: one – reflected especially in the articles by Hymes and Stanley Diamond – was the radical Boasian tradition in the work of people like Edward Sapir, Ruth Benedict, and Paul Radin, who thought of anthropology as a reflexive critique of civilization. The other strain – reflected in Eric Wolf's contribution – was a post World War II Marxism (much influenced by the cultural-evolutionary materialism of Julian Steward) which was concerned to highlight the plight of peasant societies caught in the juggernaut of capitalist imperialism.

The intellectual tradition of British social anthropology has of course a very different historical context than US cultural anthropology, one far more intimately interconnected with the subordination, management and rule of colonial subjects. Not surprisingly, then, the concerns of Asad's *Anthropology and the Colonial Encounter* were somewhat differently inflected than those of Hymes's volume. To be sure, they shared a concern that since World War II fundamental changes had occurred in the world inhabited by social anthropology. The emergence of new nations, especially in Africa where much British social anthropological fieldwork was carried out – Sudan (1956), Ghana (1957), Nigeria (1960) – made it increasingly difficult to avoid the pertinence of a more historical approach that brought the larger political and economic system of colonialism into view. And in consequence it was increasingly difficult not to be critical (as indeed Edmund Leach was in

a limited way) of the ahistorical functionalism and empiricism that characterized British anthropological theorizing.

In the middle 1960s, New Left critics had in fact launched an attack on British social anthropology. And part of the project of Asad's volume was to respond to these and other radical claims, not simply to affirm or deny them, but to more adequately specify and formulate them. There was a sense that perhaps, while undeniable, the relation between colonialism and social anthropology was more complicated than was allowed by the polemical tone of accusation and disavowal. In her contribution, for example, Wendy James argued that the very existence of social anthropology in the colonial period constituted a source of *potential* radical criticism of the colonial order, and she sought to provide a more nuanced account of Malinowski's own active social reformism during the interwar years. Stephan Feuchtwang, in his contribution, discussed the relation between the social and institutional conditions of British anthropology and the knowledges it produced. In an allied way, Asad examined 'objectifications' of colonial power produced in two authoritative domains of systematic knowledge – the functionalist anthropology of Africa and Islamic orientalism. Asad was concerned to understand the connections between these different images of rule (one largely of 'consent,' the other largely of 'repression'), their ideological roots, and conceptual consequences.

In subsequent decades, the anthropological preoccupation with colonialism has tended to be largely (if not solely) a phenomenon of the US academy. At any rate, in the 1980s there was a gradual shift away from the concern with the *role* of the discipline in the colonial/imperial enterprise and the politics of its practitioners, toward a concern with colonial forms of knowledge about non-European worlds. The register in which the problem of colonialism for anthropology was conceived was now less a political than an epistemological one. Or rather, linking power and knowledge, colonialism was now conceived as a problem of (in the language of the day) the politics of representation. This shift has many interconnected sources. I shall only be able to touch on a few of the more salient ones.

At one level, of course, the shift is connected to the decline of anti-imperialism and anticolonialism as going *politico-ideological* concerns. On the one hand, beginning with the end of the Vietnam War and accelerating through the years of Ronald Reagan's US Presidency there is a marked decline in the First World intelligentsia's interest in revolutionary change in the Third World. On the other hand, in the Third World itself there is a decline (indeed a rapid unraveling) of the experiments with radical social transformation in many of the independent countries of South Asia, Africa, the Caribbean, and Latin America. At another level this shift was connected to a number of *intellectual* transformations in the understanding and practice ofthe human sciences. Very broadly speaking, these may be characterized in terms of a general drift away from the determinism (Leslie White, Julian Steward) and functionalism (Radcliffe-Brown) of postwar anthropology and toward a social/cultural constructionism. Principal among these transformations was the so-called 'turn to meaning' in social and cultural analysis. In many ways, of course, the work of Geertz (1973) embodied – indeed, helped to constitute – this constructionist moment. In his work, culture came to be understood as a web of semiotic processes or relations, and cultural analysis as a practice less of uncovering determinate causes, or of explaining functions, as of deciphering meanings. Two features of this anthropology are of special importance here: one is that its criticism of objectivism brought about a renewed sensitivity to 'the native's point of view' and 'local knowledges'; and the other is that the critique of positivist social science led to a greater openness to interdisciplinarity, to literature and history in particular (Geertz's famous 'blurring of genres').

This work, in turn, set the stage for the emergence in the 1980s of an interest in the *textuality* of ethnographic description and analysis, in the senses in which these are artifacts of language – hence, in their way, *literary* – and therefore open to an investigation of their rhetorical and poetic structures (Clifford and Marcus 1986). How is ethnographic authority constructed? What are the linguistic devices that enable anthropological representations to produce their distinctive 'realistic' effects? Some of this work sought explicitly to reconceive the task of a critical anthropology (Marcus and Fischer, 1986).

This preoccupation with modes of representation in social and cultural analysis was, in part at least, the context for the rise of what would come to be called colonial studies. An interdisciplinary field (drawing largely on literary critics, anthropologists, and historians), colonial studies would help to institutionalize the renewed scholarly focus on colonialism. The central inspiring text here was Said's *Orientalism* (1978). Borrowing in some measure from the middle work of Foucault (1979), this book thematized the idea of colonialism as a *discursive* formation. Said set out to demonstrate the ways in which, in the (especially French and British) colonial discourse of orientalism, the Orient was invented. The Orient, therefore, was less a geo-political location than a figure in the cultural-political imagination of the West. *Orientalism* opened up a rich vein ofresearch and a critical demand to interrogate the West's authoritative discourses on the non-West – anthropology chief among them – and to unmask the ways in which they produced and reproduced their hegemonic knowledges. Interestingly Said himself (1988) would later express doubts about the value and future ofa discipline so deeply implicated in the making of such hegemonic knowledge.

One anthropological work that drew together some of these themes – though in a way less pessimistic about the possibility of a revised anthropological enterprise – was Fabian's *Time and the Other* (1983). The subtitle of the work was significant: *How Anthropology Makes its Object*. It focussed attention precisely on the 'constructedness' of anthropological discourse, specifically on the uses of Time in anthropology's constitution of its object (the savage, the primitive, the native, the Other). Fabian sought to show how the existential copresence of the Other in the dialogical interaction of ethnographic fieldwork gets transformed into a temporal distancing – what he called a denial of coevalness or cotemporality – in the theoretical construction of authoritative anthropological knowledge. This 'conjuring trick' served perpetually to consign the native to a temporal zone outside of the Time of anthropology, which is to say the privileged Time of the West. It is easy to see that the lessons of Fabian's book are wider than the issue of temporality alone. What it demonstrated was that unless anthropology subjects its own discourse to critical scrutiny, unless it pays attention to the conceptual assumptions that go into the *making* of its objects, it is liable to reproduce colonial

knowledge. Other work would later seek to extend and develop this inquiry into the formation of anthropological objects (see Scott, 1994).

Another set of anthropological concerns with colonialism in the 1980s was more closely connected to the antinomies of Marxism. The defeat of the communist project in Western Europe after 1920 had given rise to a strain of Marxism (soon to be called Western Marxism) focussed on what had hitherto been dismissed as superstructural issues. Marginalized until the rise of the New Left in the 1960s, this strain became more prominent in the 1970s, especially in the North Atlantic academy. Antonio Gramsci's theorization of hegemony, Louis Althusser's reconceptualization of ideology as representation, and Raymond Williams's displacement of the base/superstructure model for the analysis of literature (and cultural production more generally) offered less reductionistic critical languages in which to situate social and cultural life in relation to capitalism. An interest in rethinking the problem of the articulation of modes of production, and of precapitalist (and precolonial) formations was one direction of Marxist work that had actually begun earlier. But in another direction, folded into the anthropological concern with local knowledges and finite histories, this cultural Marxism offered the prospect of an antiuniversalistic account of hitherto invisible idioms of resistance to dominant power (including, of course, globalizing capital), and of hitherto unacknowledged forms of (often informal) agency in the quotidian making of histories. In their very titles, James Scott's *Weapons of the Weak* (1985), and Jean Comaroffs *Body of Power, Spirit of Resistance* (1985), offer exemplification of this interest in the anthropology of anticolonial resistance.

Throughout the 1980s history was becoming a site of profound scholarly preoccupation. Indeed within the discipline of history itself there was already a growing interest in the intersection of modes of cultural and historical representation. Work in feminist history, in particular, helped to reformulate relations between power, difference, and representation. But perhaps the most significant contribution to the argument for more than a nodding relationship between anthropology and history – and this too on the terrain of colonialism – has been the pioneering work of Cohn (1987). Cohn's essays were only brought together in 1987, under the title, *An Anthropologist among the Historians and Other Essays*, but from the early 1960s he had been urging the theorization of the intersection of history and anthropology. In a number of wide-ranging essays on British India – from concerns with the formation of historical, legal, and statistical modes of colonial knowledge, to an interest in ritualized representations of political authority – Cohn demonstrated that historical analysis of colonial rule was indispensable for anthropological understanding. This work inspired a number of innovative studies in the historical anthropology of colonial India (among them Dirks 1987). Significantly too, India was the conceptual and intellectual-political site of another important contribution to the debate about history for an anthropology of colonialism – the Subaltern Studies Collective's re-interrogation of liberal and nationalist accounts of colonial rule in India and the anticolonial struggle against it (Guha, 1984). Trans-disciplinary in perspective, the work of the Collective resonated with the anthropological discontent with universalism and Eurocentrism and its interest in the agency of non-dominant idioms, knowledges, and practices.

In the 1990s one can discern another shift in the questions driving the anthropology of colonialism. These new questions turn less on the textuality of colonial representation or the agency of resistance than on the problematization of the relationship between colonialism and modernity, and the implications of this relationship for understanding the postcolonial present (Asad, 1991, 1992; Scott, 1997). The profoundly epochal sense attending the *fin de siecle*, the sense of a crisis of modernity (and for some, an emerging *post*modernity), has made for a growing preoccupation with a re-examination of the formation of the modern world and its moral, epistemic and political modes of legitimization. Much of this re-historicizing work has sought to criticize the progressivist story of modernization.

There are several dimensions to this anthropological preoccupation with colonialism and modernity. One of the earliest has been the concern with the problem of nation and nationalism. There had of course been an older multidisciplinary interest in nations and nationalisms, namely, the 'new nations' projects of the early 1960s. These studies were primarily concerned with inquiring into the modernizing and democratizing challenges facing the newly independent nation-states. However, two books more than any others reopened and significantly reshaped the debate about the nation: Gellner's *Nations and Nationalism* (1983), and Anderson's *Imagined Communities* (1983). Each was focussed differently, but they were both inspired by the problem of the relation between nation/nationalism and *modernity*. If the 'new nations' work tended teleologically to take nationhood as a normal developmental threshold, what Gellner and Anderson foregrounded was the idea that nations were not natural entities nor nationalisms primordial sentiments or ideologies. Both, they argued, were profoundly historical, and that historical character, moreover, owed most to the making of the *modern* world.

Gellner and Anderson would both be criticized for their emphasis on the modernity of nations and nationalisms, but it was precisely this connection that those interested in colonialism were concerned to explore. Anticolonial nationalisms and the making of postcolonial sovereignties clearly had a very complex – and as yet, perhaps, unresolved – relation to the modernizing project of late colonialism. In this regard the decisive work was Chatterjee's seminal book, *Nationalism and the Colonial World*, originally published in 1986 but becoming influential in debates from the early 1990s. A noticeable feature of this work was its interdisciplinarity, and especially the place of anthropology (as the authoritative discourse on Europe's Others) within it. While indebted to Said's *Orientalism* for its opening deconstructive move, Chatterjee undertook a sustained examination of anthropological assumptions (e.g., about rationality) undergirding the distinction between Western and non-Western nationalisms.

Connected to this focus on rethinking the relations between modernity and nation, has been the renewed attention given to the problem of modern colonial power generally, and the colonial state in particular. Especially important here has been the later work of Foucault on governmentality (1991) that raised the question of the place of the state in a larger and much

transformed understanding of power. Questioning a deeply influential tradition of social and political analysis owing much to both Marx and Weber, Foucault's concept of governmentality sought to think (conceptually) about a field of power in which the state was not the central analytical domain; and (historically) about a concrete moment in European history when political power becomes more dispersed, less dependent upon the institutions of coercion. This concept opened up the possibility of reconceiving the questions through which the problem of colonial power was formulated. Where modernization narratives (liberal or Marxist) had plotted a story of the progressive rationalization of the state (the more or less of power; the counter-positioning of power and freedom), what now emerged was the possibility of a story of colonial power told in terms of the political rationalities by which it was organized. The point here was to urge an historicization in which the emergence of a colonial rationality of government (i.e., a form of colonial power directed at transforming conditions so as to produce effects on colonial conduct) could come more sharply into view. And the significance of this is that this rationality is central to the making of our postcolonial worlds (see Scott, 1999).

There have been critics, of course, who are skeptical about this thematization of governmentality in the anthropology of colonialism. The more sympathetic of them argue that neither the old master-narrative of progress and modernization nor the new Foucauldian revisionism are adequate because neither appreciates the inherent *doubleness* of colonial rule. The essential paradox of the colonial state, it is argued, is that it was always caught between *two* principal imperatives – ruling subjects and making citizens – and, therefore, always moved simultaneously in two directions: coercion and civilization. The crucial hinge on which this doubleness hung was the colonial language of law and legality (Comaroff, 1998). In a related direction some critics have been concerned that the whole relation between metropole and colony has been ill-conceived (Cooper and Stoler, 1997). The worry here is the assumption among many students of empire of a Manichaeism that sees the problem of colonialism as a binary – colonizer/colonized – one. These critics argue that, to the contrary, the conception of an encounter between an empty colony simply remade by Europe and a Europe that remains ever unmarked by its empire is untenable. They urge a view that places metropole and colony in a single (if internally differentiated) analytical field, and focuses precisely on the multiple tensions – inclusions/exclusions, hierarchies, reversals, etc. – through which Europe and its empire were (unevenly and asymmetrically) co-constructed.

Since its emergence as a distinctive theme in anthropology in the 1970s, the problematization of colonialism has been thought of as part of an orientation towards the present at least as much as, if not more than, the past. In this sense there has always been about it an animating ethos of criticism – whether criticism of our worlds or criticism of our disciplines. The anthropological problem about the colonial past, in other words, has been connected to raising critical questions about the postcolonial present: it is part of the making of a distinctively *postcolonial* anthropology. However this connection and its implications have been more often assumed than systematically thought out. Consequently, anthropology has been less concerned than it might, not merely about the ways in which understandings of the colonial past are conditioned by contemporary 'scenes of inquiry,' but more importantly about the ways in which a self- consciousness about alterations in the latter ought *strategically* to alter the kinds of questions we pursue about the nature of the former. The point, then, is that for anthropological criticism to have purchase on the present it is not enough to insist that the purview of colonial studies be enlarged (to encompass Europe, for instance, or gender, or the state), it is necessary to specify the domain of contemporary questions that are being addressed in so doing. This is the only way to gauge the extent to which our critical exercises are meeting a contemporary demand as opposed to simply expanding an already established cognitive field.

This is the challenge. It is an important challenge because the crisis upon which the formerly colonized world entered in the 1980s and 1990s (unlike those of the 1960s and 1970s) is a crisis not merely of policy orientations or development options or even ideological alternatives. It is a crisis of the legitimacy of the modern/modernizing assumptions that have undergirded the very making of these colonial and postcolonial societies and polities (assumptions, for example, about the relation between culture and politics; between nation and sovereignty; between individual rights and historical traditions, and so on). Our *conjuncture,* in short, is shifting. And therefore, if it is to more adequately theorize the relation between the problem-space in which it produces knowledge and the questions through which it does so, the anthropology of colonialism has to attend more systematically to the changing contours and character of this postcolonial present and its crisis.

Abstract

This article begins with an exploration of the semantic field of 'colony' and its theoretical implications. On this basis, an outline of the history of colonization and colonialism hints first at analogous cases in antiquity and elsewhere in world history, then describes European expansion since the early Middle Ages down to twentieth-century imperialism. Next, a typology of expansion processes, of individual motives of participants and of colonies is presented. Finally, after the history of decolonization, the consequences of colonialism in the postcolonial world are discussed, postcolonialist theory included.

Introduction: Problems of Definition and the Semantic Field

"Colonization is […] a phenomenon of colossal vagueness" (Osterhammel, 1995: p. 4), because it covers large and rather different parts of the world and its history. Therefore, a convincing theory of colonization and colonialism in general or of European colonialism in particular does not exist and will probably never exist, because it is not feasible. But scholars have still to define the concepts they use, because an agreement upon their meaning makes communication possible. Colonization has to do with migration, because it describes the movement of people from one part of the world to another to establish a settlement, quite often an agrarian one. In this sense, the term has a neutral connotation. In contrast, colonialism has become a general invective against Western policy, especially since the Bandung conference of recently decolonized Asian countries in 1955. In the nineteenth century, however, it was used more or less neutrally to characterize the condition of colonies and the (speech) habits of colonials (Fieldhouse, 1981: p. 6). One has no choice but to accept the change of meaning that colonialism has undergone, although one can try to neutralize political emotions. In this sense, colonialism can be defined as the control of one people by another culturally different one, an unequal relationship that exploits differences of economic, political, and ideological development between the two (Reinhard, 2008: p. 1). Even in European countries, unbalanced internal group relations as in the case of Britain's 'Celtic fringe' were qualified as internal colonialism (Hind, 1984). People instead of nation or state is used because basically no sophisticated political organization is necessary on either side. And the terms difference and development are used in a strictly descriptive sense and without any value judgment. They do not suggest that it is more desirable to have nuclear weapons instead of bow and arrow or that there exists a general and 'normal' path of human development with the West at the end. But differences of development are essential to distinguish colonial rule from empire in general. Roman rule over ancient Greece and Russian control of East Germany were imperial, not colonial.

Nevertheless, colonial empires are still a variety of empire in general. One uses empire worldwide to designate any large political unit before the modern state reached its maturity in Europe and started to expand from there. In contrast to the state's homogenous structure and consequential outstanding concentration of power, empires remained loosely structured and more often than not organized in concentric circles of decreasing control by the center. The Ottoman Empire, China, Siam, Madagascar, and initially also Japan remained empires in that sense, whereas during the eighteenth and nineteenth centuries their European counterparts became powerful modern states. Their notorious superiority enabled them to build up additional colonial empires around the hard core of European national power states. Only this exceptional unbalanced constellation made ephemeral European world hegemony possible. In addition, Western colonies in the Americas, in South Africa, and in Australia established a secondary colonialism in their parts of the world.

Colonialism, as an unequal relationship between human groups, very often was the outcome of imperialism, defined as a political activity with the intention to establish colonialism, in other words, a colonial empire. But if the meaning of imperialism is limited to expansive policy of the nineteenth and twentieth centuries, colonial expansion has to be used to designate earlier policies. Only the similarly unbalanced power relations between Amerindian stone age empires and Iberian monarchies allowed the formation of colonial empires in the New World as early as the sixteenth century.

During nineteenth-century European world hegemony colonialism changed, under certain conditions, into the varieties of informal control or even of informal empire. Semi-colonies such as China or the Ottoman Empire about 1900 were formally independent but in reality under the economic and therefore also political control of the West. In contrast, in the nineteenth century, West Africa under British paramountcy was a case of informal empire. After decolonization, colonialism as a form of political dependency has become a mere phenomenon of history. But economic and cultural domination by former colonial powers such as Britain and France on the one hand, and by the United States and the US-controlled world economy on the other, still exists. It has been labeled neocolonialism. In the 1960s and 1970s, theories of structural dependency explained economic underdevelopment as a consequence of Western economic domination and as self-reproducing without chance of escape because of Western control of the world economy. Several success stories of former

colonies such as Brazil or Taiwan have falsified these theories, but their lesson on informal control as an element of colonialism remains.

The History and Geography of Colonization and Colonialism

The expansion of Europe between the fifteenth and twentieth centuries was one of the most momentous processes of history. World history in the sense of global history became possible only through that process, because no part of the world escaped the direct or indirect impact of Europe. In 1914, half of the land surface of the earth and one-third of its population were still under direct colonial rule. But this was only the last chapter of a long story, because colonization and colonialism are essential components of history in general, especially, if one does not omit continental expansion in Russia, the Americas, and elsewhere in favor of overseas colonialism. Colonization in the sense of expansion of settlement and agrarian land use could even be considered the quintessence of human history before industrialization. Chinese colonialism is perhaps the most remarkable case because of the relative continuity of Han-Chinese expansion starting from the lower Huang basin thousands of years ago and leading to the present penetration of Tibet, Mongolia, and Xinjiang. The ancient world of the Mediterranean was full of Phoenician, Greek, and Roman settlement colonies.

Europe was expansive right from the outset; it was a creation of its own expansion. To a large extent, European history consists of successive waves of expansion. The Vikings were followed by colonization in Eastern Europe. People from central and Western Europe settled in the East, a process to be continued by Russia in Siberia until the Pacific Ocean was reached. The French who were excluded from the colonization of the East became protagonists of the crusades instead. The first European colonies established by the crusaders in today's Middle East were a failure. But in the same context, Italians developed a system of maritime trade and factories combined with the colonial production of high-value commodities such as sugar. For some time, they participated in a world trading system extending from Greenland to China. On the other hand, Spain and Portugal colonized the reconquered South of the Iberian Peninsula and the Canaries, whereas England did the same in Wales and Ireland. Such experiences of the Middle Ages became predecessors and models of the later expansion of Europe. Not by chance America was 'discovered' by a Genoese and 'baptized' after a Florentine in the service of Castile.

Beginning in 1415, the Portuguese followed the coast of Africa until they found their way to India in 1498. To control the spice trade of the Indian Ocean, they established a trade empire based on fortified ports, factories, and colonial rule over spice producers such as Ceylon and the Moluccas, extending from East Africa to China and Japan with Goa in the center. During the European conflicts of the early seventeenth century, the Dutch East India Company, in contrast to Portuguese crown capitalism a privileged private corporation of shareholders, conquered most of the Portuguese system, but established a new capital in Batavia on Java. Arriving at the same time, the French and English East India Companies created their bases on the coast of India, a comparative advantage when European demand changed in the seventeenth century and Indian textiles became the leading commodity. In the eighteenth century, they were replaced by tea and coffee with the China trade as core business. But trade remained under strict control of the Chinese and Japanese empires and 'Western barbarians' were only tolerated until the middle of the nineteenth century when China and Japan were 'opened' for free trade by Western military aggression. On Java and in India, however, the Mataram and Mughal empires began to disintegrate in the eighteenth century. This led to the control of Java by the Dutch and the conquest of all India by the British. Already in the later eighteenth century "the parallels with today's corporate leviathans soon became overpowering, with the Company outstripping Wal-Mart in terms of market power, Enron for corruption and Union Carbide for human devastation" (Robins, 2006: p. XI). Most of it was the result of contingency, but besides the interest in profits the ambition of local European military, the 'men on the spot,' was a constant factor. For some time, they could also rely on the superiority of soldiers drilled in the European way.

Discovery and colonialism went hand in hand down to the twentieth century. Since 1492, Castilians competing with the Portuguese discovered and conquered their India in the West. Spaniards emigrated to live in the cities of a New World. But despite a tremendous loss of native population, mostly through infectious diseases imported by the conquerors, the labor force consisted mostly of Amerindians, especially when, after the discovery of silver mines in northern Mexico and highland Peru, America became the treasure house of the Spanish monarchy. A protobureaucratic system of colonial government was established instead of traditional feudal lordship desired by the conquerors. In theory, the Spanish empire consisted of territories with equal legal status. The term colony was not used for overseas possessions before the eighteenth century. But Iberian America was to remain a racially stratified society. Metropolitan Spain did not profit much from American silver, which, because of differential inflation rates and overambitious policy, flowed out of the country to feed the Asian trade of the Dutch and the English. Via Europe and directly via the Philippines, much of the American silver ended up in India and China and favored economic and political growth there. A kind of world trade system originated, but probably with rather marginal economic impact on Europe and on Asia. Brazil became a Portuguese colony almost by chance, economically important only in the later sixteenth century when sugar cane was grown on its abundant fertile soils. Indian labor was scarce here but the Portuguese controlled the opposite coast and therefore were able to provide the sugar industry with African slaves. When the sugar cycle reached its end, gold and diamonds created a new boom in Brazil during the eighteenth century, but with similar negative consequences for Portugal as for Spain 200 years earlier.

In the seventeenth century, the Dutch transferred the Brazilian plantation economy to the Caribbean where the English, French, and Dutch had conquered several islands from Spain. No Amerindian labor force was left there, but the Dutch had occupied some of the Portuguese strongholds on the West African coast with the British and the French to follow. Thus, the West Indies could be provided with African slaves. The

English were the leading slave traders of the eighteenth century when the sugar business reached its culmination point. Large parts of the Caribbean were converted into an agroindustrial complex with a completely artificial society of black slaves, white lords, and an increasing number of mulattos.

In the meantime, another type of artificial new world had originated in North America, which in the long run became a white man's country, the first and most successful of several 'new Europes' created by about 60 million Europeans who emigrated between the sixteenth and twentieth centuries. North American Indians were few in number and not able to defend the land white immigrants desired. French Canada with its small settler population could at least attempt their integration, whereas British North America had no room for them. They were removed, marginalized, or wiped out. Around 1780, British North America had more than 2.6 million inhabitants, compared with about 8 million inhabitants of England and Wales.

In 1775–1823, Europe lost most of her American colonies. But Britain, which dominated the colonial scene for most of the nineteenth century, compensated for the loss with the conquest of India and with several new colonies, some of them acquired during the wars against France, like Canada and South Africa, others new foundations in Australia and New Zealand, which had been explored during the late eighteenth century. But they were accepted rather reluctantly, because in an age of British-dominated free trade colonial rule was considered unnecessary and too expensive. Therefore, self-financed self-government of white settler-colonies was now welcome. Between 1840 and 1931, these British 'dominions' became quasi-independent. This was the age of the so-called free trade imperialism when political pressure and military violence were used only exceptionally where free trade relations had to be enforced as in the cases of China and Japan (Gallagher and Robinson, 1953).

This relaxed attitude was to change in the age of imperialism, when steamships, deep sea cables, telegraph, and finally wireless transmission improved worldwide communication and Western superiority increased tremendously with military technology such as the machine gun (Maxim gun). Now, nervous competition of old and new powers under the ideological impact of nationalistic social Darwinism led to the division of Africa within a few decades based upon the legal fiction of *terra nullius* (land belonging to no one) and the right to take possession of such supposedly unoccupied territory. Most of what was left of Asia was also occupied or at least controlled economically. Governments were now much more engaged in colonial activities than ever before. Besides Britain's notorious rival France and the old colonial powers Portugal and Spain, new competitors entered the stage: Russia and the King of Belgium, Germany and Italy, the United States and Japan, the first non-Western imperialist power, which a few decades earlier had been close to becoming a semicolony. After World War I, the German colonial empire and the Ottoman Empire were divided among the victors. The formal qualification as mandates of the League of Nations did not make much difference. Neither was the League of Nation able to prevent the Japanese occupation of Manchuria in 1931–32 and the Italian conquest of Ethiopia in 1935. Ethiopia had defended herself successfully against Italian aggression in 1896, but as the last African country had to yield to colonialism – if only for a few years. Times were beginning to change.

Less spectacular than expansion overseas, and therefore often ignored by historians of colonialism, was the 'quiet' continental expansion of Russia and the United States; of Canada, Australia, and South Africa; and of Brazil, Argentina, and Chile. This expansion was possible only at the expense of indigenous populations and through the exploitation of differences of development. This turned out a very effective variety of colonialism, because the result was most often a white man's country, another 'new Europe,' where the former population was marginalized or wiped out. Only in few cases such as South Africa, Russian Central Asia, and Caucasia, non-Western groups were numerically and culturally strong enough for later successful decolonization.

Typology of Colonization and Colonialism

There was no master plan for colonial expansion. Quite often, it happened as unintentional consequence of some other action. Nevertheless, typical sequences of actions occurred again and again, for instance, preventive occupation to keep out possible competitors. The Portuguese used this in sixteenth-century Brazil, as did most European powers in nineteenth-century Africa. Military intervention in Africa was sometimes not intended as permanent occupation, because it was much too expensive. But when African resistance made a retreat impossible without loss of national prestige, the temporary occupation became a permanent colony. If not a matter of prestige, colonial policy was always based on a kind of cost-benefit analysis. Colonies were expected to be profitable. At least they had to finance their own government. The famous British model of indirect rule did originate much less from political wisdom or respect for other civilizations than from the necessity to keep administration costs down. In reality, national budgets only profited from colonial empires in exceptional cases, because infrastructural costs were considered the responsibility of the government, whereas colonial profits remained private.

The most common individual motives for participating in colonial activities were indeed the desire for extra profits and the improvement of social status. These were certainly not the only motives, but they were almost never absent. Of course, their character changed over time. The conquerors of British India were capital accumulating profit seekers, but like those of Spanish America still with the intention to invest in social status and not in capitalist enterprise in the way of the nineteenth and twentieth centuries. The second most common motive, missionary zeal, also changed over time. Instead of spreading the gospel and European civilization, modern colonizers followed the urge of a civilizing mission to educate barbarians. They fought slavery and tried to transform 'lazy natives' into industrious workers. In the age of imperialism, however, it became common conviction that inferior races could not be 'improved,' but were doomed to serve or to die. Thus, colonial adventurers could feel entitled to pose without restraint as the master race.

From the fifteenth to the twentieth century, colonies usually represented one of three basic types, sometimes as a mixture.

1. Trade and/or military bases such as the stronghold system of the Portuguese trade empire or Britain's naval bases in the nineteenth century or the frontier forts of the United States. Spanish ecclesiastical missions such as the Jesuit reductions of Paraguay sometimes served a similar purpose. Of course, systems of bases were also an essential part of informal empires.
2. Colonies of settlement, probably the primitive type of colony, especially when combined with a kind of stronghold as in the case of the Roman 'Colonia.' Larger settlement colonies could only be founded at the expense of indigenous people who were either removed (New England) or transformed into a dependent labor force for an 'improved' economy (Spanish America and South Africa) or replaced by workers of foreign origin (Africans in the Caribbean and East Indians in Guyana).
3. Colonies of exploitation with only a small number of members of the ruling people present most of them only temporarily, to run business, administration, and defense. Parts of colonial Latin America resembled that type, but it became the dominating type during nineteenth- and twentieth-century colonialism with British India as the prototype and much of Africa to follow. The administrative penetration of this type of colony tended to be rather limited.

In consequence, colonies of exploitation could not be ruled without massive collaboration from the indigenous people (Robinson, 1974). But collaboration had already been a necessary precondition for the Spanish conquest. In colonial wars, natives quite often fought on both sides. To consider such collaborators as traitors, however, is an anachronistic value judgment of modern nationalist historiography. People like the Tlazcaltecans quite rationally served their own interest regardless of a Mexican nation that did not yet exist. Recent research on the colonial situation from the perspective of people under colonial rule has corrected such simplifications. Non-European history no longer looks just like an inversion of the eurocentric pattern when the colonialist image of benevolent Western heroes ruling inferior races for their own benefit is simply inverted in the anticolonial story of Western rascals systematically abusing helpless non-Western victims. To some extent, the image of the helpless native itself is a creation of latent racism. In reality, a broad range of options to cope quite successfully with colonial domination was available to indigenous people, to some extent even to African slaves. The traditional contrast between colonial lords as active initiators of colonial processes and colonial subjects who had no choice but to suffer passively or at best to react against the actions of their betters has been questioned. But to believe after decolonization that colonial rule was only a short episode without much impact on the colonies seems to be an anticolonialist oversimplification, even in Africa.

Decolonization

The term decolonization was created in 1932 (Albertini, 1966: p. 28) but the process is much older. A first wave of decolonization, the independence movements of most American settler colonies and of the Afro-Americans of Haiti 1775–1823, reduced European colonial empires drastically. But Britain at least knew how to compensate for these losses. On the other hand, some lessons of the first wave were learned and made the second wave, the gradual increase of self-government in Britain's white dominions 1840–1931 much more easy going. Between the World Wars, anticolonial movements emerged in several exploitation colonies, with British India in the lead. Japanese occupation of Asian colonies during World War II fostered independence movements that were successful after the war in a third wave of decolonization in the 1940s and 1950s. At that time, Africa was apparently not yet ready for decolonization. Colonial powers once again tried instead to compensate for their losses in Asia by economic development of their possessions in Africa. However, under growing political pressure, some African countries became independent in the 1950s, and most in what was the fourth wave of decolonization during the 1960s. A fifth wave began in the Portuguese colonies in 1974–75 and accelerated political change in South Africa. But the sixth wave of decolonization in the 1990s, this time internal, included not only the end of South Africa's white minority regime, but also quite unexpectedly the breakdown of Soviet rule in Central Asia and Caucasia and Israel's first attempted arrangements with her Arabs.

Decolonization was a truly dialectical process, because colonial rule produced its own contradiction, which is politically frustrated new indigenous elites. Everywhere, Westernized groups and not the traditional authorities were in the lead of independence movements. But an independence movement or even an independence war was not enough. In most cases, a triangular constellation of political factors was the essential precondition; besides an internal independence movement, favorable international conditions such as allies, anticolonial policies of the world powers, and the United Nations, and the willingness of the colonial power to accept the unavoidable were also necessary.

The Consequences of Colonialism and the Postcolonial World

It is simply not true that colonial processes left no impact on former colonies. The postcolonial world is not the same as before, even in Europe. Several American plants, the potato in particular, became essential for Europe's population and economic growth. Colonial bullion and colonial profits contributed to the rise of Europe, if rather marginally and indirectly. They were certainly not the sufficient precondition of industrialization. Colonial problems influenced European power relations, but rarely dominated them. Europe assimilated new cultural elements from all over the world, but without changing her character. In the colonies, however, ecology, economy, politics, society, and culture often changed more thoroughly, sometimes even fundamentally. However, this does not imply a one-sided modernization directed by Europe but rather processes of interaction.

Intentionally or unintentionally, colonial rule has transformed ecological systems. After new plant foods had been introduced, American savannahs changed into corn fields suffering from soil erosion and new weeds. Domesticated animals formerly unknown in the Americas, Australia, and

New Zealand revolutionized working and eating habits, transportation systems, and even the whole way of life of such groups as the Indians of the North American plains. Unknown infectious diseases killed millions who were replaced by an artificial population of immigrants and imported slaves.

The deliberate diffusion of European and especially American cultivated plants such as maize and manioc over Asia and Africa created a new agriculture and allowed an expansion of food production, a necessary precondition of modern population growth in the colonies. But colonial economies were first of all based upon the systematic exploitation of mineral resources such as American silver, African diamonds, gold and other ores, and more recently of oil in the Middle East and other parts of the world. In addition, they specialized in the production of high-value agrarian products such as sugar, coffee, and tea on large plantations. Colonial railways were a harbor-centered instrument of this export economy. Mines and plantations more often than not ruthlessly exploited a colonial labor force of slaves and contract and forced laborers. Because, as a rule, colonies could not industrialize, their independent successor states remained dependent on the world market price of their raw materials, which only in the case of oil took a turn to their advantage with lasting consequences.

The essential political heritage of colonialism is the modern state with its legislative, administrative, judicial, military, and educational apparatuses. Every former colony has changed into a modern nation-state, but strictly within the arbitrary and sometimes absurd colonial border lines. Therefore, some are extremely poor and very few are powerful enough for an independent foreign policy. But in contrast to former periods of history, weak states today have their existence guaranteed by the international community (Jackson, 1990). Internally, only few of them can build upon the tradition of a historical community. And instead of a modern civil society, their colonial heritage is ethnic fragmentation, to some extent artificially created by colonialism. Quite often, they had no alternative to the language of the former colonial power as national language. Under these circumstances, the modern state in general and Western democracy in particular could not become a success and were replaced by the parastateliness of self-organizing groups based on remarkable combinations of traditional and modern elements. Without generally accepted legitimacy and reliable civil servants, the political leaders had little other choice but to rely upon a neo-patrimonial system of clients and upon the military.

Everywhere, colonialism has created new social groups living in Western-style urban environments: workers and employers, school teachers and professionals, and civil servants and professional soldiers. Women have found new roles and quite often emancipated themselves from traditional restrictions. All this is based on Western science and technology, on Western ideas and ideologies like rationalism and individualism, the rule of law and human rights, and Christianity and socialism. From this state of things, so-called postcolonialists have drawn the conclusion that political decolonization may be more or less finished and economic decolonization well under way, whereas mental or cultural decolonization has not even begun because nowadays nobody outside Europe is able to think in a non-European way. Even attempts to deconstruct this state of things have no choice but to employ intellectual instruments of European origin. However, paradoxically their very assessment of the interaction of colonizers and colonized in terms of hybridity, of third space, of in-between demonstrates that it is completely inadequate to assume a lingering continuity of mental colonialism. Because this state of things no longer implies cultural dependency, but rather the opposite: non-Western people in the meantime have appropriated a cultural heritage of Western origin. For example, the role of English as common language of the world stems from historic British and American dominance. Increasingly, however, the acceptance of 'new Englishes' all over the world indicates that the Anglo-Saxons have been expropriated of their language.

Color Classification and Symbolism

Abstract

The history of research into color classification is traced, looking at both the variation of linguistic categorization *of* colors in different cultures and at the work of anthropologists concerned with classification *by* colors and its symbolic meaning. The triadic classification by colors (black, white, and red), which is especially prevalent in sub-Saharan Africa, is discussed. The color triad is interpreted as a device for philosophical categorizations and the 'magic' or 'sacred' power of red is noted in other contexts – such as within the Christian church. However, any combination of colors from the triad may have different concrete references in different situations in both Europe and Africa.

'Color classification' is an ambiguous concept. It may refer to 'classification *of* colors,' or 'classification *by* colors'. Most research on color classification has opted for the first approach, which is concerned with the variation of linguistic categorization of colors in different cultures. This kind of research has been undertaken by linguists, psychologists, and cognitive anthropologists. By contrast, the few anthropologists who have opted for the second approach have been concerned rather with symbolic anthropology, or have worked in a structuralist tradition of sociocultural anthropology. Research into color classification has a long history, dating back to the 1870s (Allen, 1879; Gladstone, 1877; Magnus, 1877). However, it was not until Berlin and Kay published their seminal book on basic color terms (1969) that research in this field virtually exploded, especially within cognitive and linguistic anthropology. Over the last 25 years, a wealth of data on color categories has been meticulously collected in different parts of the world, mainly with the help of the 'Munsell color chips.' As a general rule, randomly chosen informants have been asked to define the colors on these chips, and to 'map' them. The findings have then been tested as 'hard data,' often using quantitative methods (e.g. MacLaury, 1986; Kay et al., 1991). This 'hard-wire' approach to color classification research has been further strengthened by the general assumption that color perception is a matter of neurobiology, universality, and evolution.

Although the evolutionary paradigm had featured in research on color classification for almost 100 years, Berlin and Kay were the first scholars to present substantial evidence for a theory concerning the universality and evolution of basic color terms. In the original formulation of their theory, they defined a particular sequence of developmental 'stages' of basic color terms, and suggested that these stages would correspond to the stages of technological evolution. The few cultures in which only two basic color terms were used would represent Stage I on the evolutionary ladder, while the prevalence of three color terms would place a particular culture one step higher up (Stage II). Four basic color terms would imply Stage III, five terms Stage IV, and so on. Societies with the maximum number of color terms (11) would represent the highest level of technological evolution.

Although Berlin and Kay have modified the original formulation of their theory (Kay et al., 1991), the main features of the paradigm have been generally accepted by scholars in their own and related fields. Part of the reason for this is that Berlin and Kay backed up their theory with a wide range of cross-cultural linguistic data, which showed a remarkable regularity with respect to the sequence of basic color terms: if only two terms were found in a particular culture, they were invariably white and black. If three terms were recognized, these were always white, black, and red. The fourth basic color term to be introduced was either yellow or green, the fifth either green or yellow, the sixth blue, and so on. In spite of some revisions and later developments of the theory (see Hardin and Maffi, 1997; MacLaury, 1999), there is still a general consensus among anthropologists about the sequence of basic color terms – even though the hypothesis about a corresponding technological evolution has yet to be proved. It would, for example, be difficult to maintain the theory about technological evolution, given that many hunting/gathering societies recognize more basic color terms than agriculturalists. In Africa, even the most sophisticated Bantu-speaking agriculturalist and agropastoral societies have only three basic color terms, whereas their hunting and gathering neighbors may have five or more.

However, strictly cognitive and linguistic research on color classification has met with criticism on several other accounts. The main criticism has been leveled at the 'hard-wire' methods employed in this kind of work, and at the lack of 'emic' approaches to the issue of color classification. It has been argued that the 'meanings' of color terms cannot be evaluated adequately when the data have been collected under conditions reminiscent of a laboratory situation (Saunders, 1999; cf Tornay, 1978), and that 'affective features of meaning' may contribute to Berlin and Kay's evolutionary sequence of color terms (Osgood et al., 1975; Taft, 1997). The problem of 'meaning' is perhaps the most controversial issue associated with the concept of color classification. Though a few representatives of the 'hard-wire' approach have attempted to account for the 'meanings' of individual color terms (Kay and McDaniel, 1978; MacLaury, 1992), the focus has still been on the implications of the informants' task of 'mapping' color chips (Lucy, 1997: p. 327). By way of contrast, Lucy directs attention to Conklin's pioneering work on color categories in the 1950s (Conklin, 1955). Applying a structural approach, Conklin discovered that the four-color categories recognized by the Hanunóo corresponded to an underlying four-way classification of other visual stimuli as well.

Conklin's findings correspond to the ideas proposed by the Swiss-French school of semiology, as represented by Saussure and Derrida. According to them, the meanings of signs depend on their positions in a larger system of signs (Layton, 1997). Meanings are thus anchored in the syntagmatic relations among signs, but if we also take into consideration the meanings which Barthes (1967) has referred to by the concept of 'the symbolic relation between the sign and the signified,' it may be possible to identify congruities of symbolic meanings when 'parallel' syntagmatic sequences of signs are compared. Such a 'parallel' structure of signifying, syntagmatic sequences of signs may be referred to as a paradigmatic structure of meaningful categories.

To identify such paradigmatic structures in cultural symbolism is the core of anthropological research on symbolic classification. This approach has characterized symbolic anthropology since the late 1960s. When colors have been included in this kind of symbolic analysis, the research has thus been concerned with classification *by* colors, rather than *of* colors. However, at the same time as this structurally oriented research developed, there was also a growing awareness among some anthropologists of the importance of contextualization in the study of symbolic meanings.

The pioneering research in the domain of symbolic classification by colors was carried out by Victor Turner, who in 1966 wrote an article on the symbolic meanings of white, black, and red among the matrilineal Ndembu of Zambia (Turner, 1966). Not only did Turner attempt to trace the basic symbolic meanings of the three colors, he also analyzed their variable references in different ritual and social contexts, and thus became one of the first anthropologists to put contextual analysis of cultural symbols on the agenda.

Turner's article stirred up an enthusiastic interest in color classification, especially among anthropologists working in the structuralist tradition. No matter whether the anthropologists found two, three, or four colors to be key symbols in a particular culture, they usually attempted to identify a dualistic system of symbolic classification, of which the colors formed a part. Thus, for instance, most of the contributions to Needham's book on dual classification included references to colors as 'parallel' devices of classification, alongside the right/left division that was the main topic of the book. While the concept of 'paradigmatic structures of signs' was not mentioned, there was an insistence on the congruity between different levels of symbolic classification. In many articles referring to different areas of the world, colors were regarded as part of this dual classification.

Needham's book was cast in the kind of structuralist tradition that marked the 1970s, and which was inspired by Levi-Strauss (1963). The basic assumption was that human beings everywhere tend to classify their world into binary oppositions. However, even if a dualistic approach could account for the choice of two opposing categories of classification in certain specific situations in any society, it cannot solve the enigma of triadic classification, which is typical of the ritual use of colors in many parts of the world.

In most African cultures south of the Sahara, triadic classification by colors appears to permeate the ritual practice of healers and diviners (Baumann, 1935; Straube, 1960; White, 1961; Ngubane, 1977; Jacobson-Widding, 1979; Kirby, 1999). This applies particularly to the Bantu-speaking societies, where only three basic color terms are recognized, namely white, black, and red. In a systematic investigation of the symbolic references of the three colors in the matrilineal belt of Central Africa, Jacobson-Widding (1979) found that the only situations in which all three colors were visually represented were in connection with certain rituals, when the ritual specialist manipulated the colors as symbols with particular, contextually dependent references. In profane contexts in which the official ideology of social and moral order was referred to as a matter of principle, on the other hand, white and black were the only colors demonstrated (cf Jacobson-Widding, 1991). In Central Africa, there is even a formal prohibition against showing the color red in such contexts, for instance in connection with lawsuits. This implies that white and black are contrasted as binary oppositions only in certain contexts, like those in which the dominant structure of order is supposed to be manifested, and in which the rationality of a logic based on two opposite values is to be applied. In contrast, red is represented in situations where indeterminate values are dealt with, and where a simplistic two-value logic would fail to account for the truth.

The concrete references of the color red may vary according to the context. However, whatever tangible phenomenon it may refer to in any particular situation, most ritual experts in central and southern parts of Africa will employ this color when they wish to represent ambiguity. In particular, red is used to represent phenomena that seem to defy classification into any of the 'officially' recognized categories of determinate values that are represented by white and black. Such phenomena, or states of affairs, may consist of bewildering emotions, anomalies, or mysterious spirits. Or they may be 'twilight' situations like dusk and dawn, birth and death, or any state of 'betwixt and between' – such as the state of initiands in a bush camp, or the state of adolescent girls, whose bodies are painted red during a period of seclusion. In essence, the color red can be viewed as a symbol of the kind of ambiguity that may result from conceptual boundary crossings. That is, when a particular phenomenon, or state of affairs, is considered to blur the boundaries of the concepts on which a 'rational' order is based, it is depicted as 'red.' This implies that the color red is associated with irrational feelings, and with the unknown.

Considering the ways in which ritual experts in Africa tend to interpret and manipulate colors, we may regard the color triad as a device for philosophical categorizations. At the most general level of meanings, the color triad appears to classify different kinds of phenomena according to three basic values of truth and morality. Whereas the combination of white and black is supposed to represent clear-cut values as logical opposites (i.e. 'good' vs 'bad,' 'true' vs 'false,' 'us' vs 'them,' 'sky' vs 'earth,' and so on), red will be introduced when the logical boundary distinguishing A from B is impossible to define. The color red will thus represent a third, indeterminate value, which can be classed neither as A, nor as B (nor as non-A), but rather as C (cf Leach, 1975).

This implies that the two-value logic of the Aristotelian philosophy of knowledge is supplemented with a third term, which in the case of African ritual practice is regarded as an *a priori* neutral value, in relation to the determinate values of truth and morality. However, this 'three-value logic' is assumed to be valid only in ritual thought and praxis, and not in

contexts where profane, 'rational' reasoning is supposed to be applied.

Since red is used to symbolize an unknown factor, which by definition is initially value-neutral, this color will be associated with unknown potentialities and acquire a dynamic quality. Accordingly, it is sometimes associated with powerful emotions, sometimes with 'magic' power – a magic power that many people may regard as dangerous, polluting, or taboo, whereas others may associate it with miracles and miraculous healing. It is this 'magic' power that is exploited by the ritual expert in Africa, whenever he or she manipulates the color red in any of the many possible combinations or oppositions with white or black. As a general rule, the ritual expert will begin any 'sacred,' ritual seance with a visual demonstration of all three colors, as if to show the cards he or she intends to play with.

If we understand the concept of 'magic power' in a broad sense, some of the African associations of the color red may also be discerned in sacred rituals outside Africa, even within the Christian church in Europe. When red is combined with white, it usually points to connotations of the 'sacred,' or the 'holy.' Correspondingly, we often find that the combination of white and black is resorted to in situations where the order of society, or its moral dogma, is supposed to be demonstrated – not only in Africa, but in Europe and other parts of the world as well. However, whether used to represent 'sacred' values in the church or 'profane' values in the courtroom, any combination of colors from the triadic set of symbols constituted by white, black, and red may have different concrete references in different situations, in both Europe and Africa. The 'meanings' of these colors as culturally instituted symbols are thus to be found on different levels of interpretation. Colors may be used as concrete signifiers with context-dependent meanings and, at the same time, as representations of more general values of 'truth' and 'power.'

Abstract

The study of the linguistics of color terms has mostly been concerned with isolating the 'basic' color terms of a language: the smallest set of linguistically simplex expressions of the language with which a speaker can name any color.

The words that different languages use to name colors have furnished a prime focus for research on the doctrine of *linguistic relativity*. This doctrine holds that (1) different languages categorize the world very differently and (2) the nonlinguistic thought and behavior of different peoples are deeply influenced by these differences in linguistic categorization. Words for colors have been considered an ideal area of lexicon for testing this doctrine because there exist scientific color order systems, which provide a precise metalanguage for describing color sensations independent of the words of any natural language. Such a metalanguage furnishes the means to characterize precisely the sameness or difference in meaning of color words in different languages.

Restricting the Domain

It is clear, however, that every language has immense – probably infinite – resources for denoting color sensations. First, every language so far studied can productively create complex expressions, which describe the color of an object by indicating similarity to another kind of object that is known to saliently display the color. An example from English is 'like the color of a male mallard duck's neck feathers.' (Although most languages do not have a word that straightforwardly translates the English word 'color,' the speaker of such a language who wishes to characterize, say, a kind of fish as mallard green can usually say that, for example, the fish 'looks like' the neck feathers of a male mallard, relying on context and background knowledge to provide the interpreter with color as the relevant dimension of visual similarity. Although relativist critiques of color naming research have maintained that absence of a word meaning 'color' in a language indicates that its speakers see and/or conceive of colors very differently from, say, speakers of European languages, the experiences of workers who have actually studied color vocabularies in the field do not provide significant support for this claim See, e.g., Conklin, 1955: p. 340; Turton, 1980: p. 322). Second, many language have words like 'blond' or 'bay,' which denote a color only as restricted to a class of objects (hair and horses, respectively). Third, many languages have morphological and syntactic processes which create complex color terms out of simple color terms. English examples include 'blue–green,' 'yellowish,' 'pale reddish purple,' and so on. Finally, some languages, English included, have many linguistically simple terms which denote subtypes or 'shades' of colors denoted by other simple terms. For example, 'scarlet,' 'crimson,' 'vermillion,' 'puce,' 'magenta,' 'burgundy,' and 'maroon' are among the more commonly named shades of 'red.' The linguistics of color terms has become a focus of research and a source of controversy in part because of the practical need to arrive at a manageable set of 'color terms' in each language to enable comparative study.

Color Terms and Linguistic Relativity

Before taking up in greater detail the ways researchers have attempted to delimit the linguistic domain of color, it is useful to consider briefly the role color naming has played in the long-running debate over linguistic relativity versus semantic universals (q.v.). In the second half of the nineteenth century it had become common knowledge among scholars that the major color words of different languages were not always perfectly translatable into one another. To some, this represented prima facie evidence of biologically based, perceptual differences among different groups of human beings, in fact the last traces of Darwinian evolution observable among humans. For example, William Gladstone, Homeric scholar and Prime Minister of Britain, observing differences between the color words of classical Greek and the modern European languages, wrote,"… the organ of color and its impressions were but partially developed among the Greeks of the heroic age" (1858: pp. 457–499).

Although this view was widespread in the late nineteenth century, it was not unanimous. For example, in order to study the discrimination and naming of colors independently, the German ophthalmologist Hugo Magnus circulated a questionnaire to missionaries and traders with 10 standardized color samples and instructions for using them in the 1870s. These instructions contained an explicit warning that failure of a language to distinguish lexically between two colors did not necessarily imply that speakers of that language did not distinguish the two colors perceptually. Magnus received completed questionnaires on 25 African, 15 Asian, 3 Australian, and 2 European languages. He concluded in part, "As regards the range of the color sense of the primitive peoples tested with our questionnaire, it appears in general to remain within the same bounds as the color sense of the civilized nations. At least, we could not establish a complete lack of the perception of the so-called main colors as a special racial characteristic of any one of the tribes investigated for us. We consider red, yellow, green, and blue as the main

representatives of the colors of long and short wavelength; among the tribes we tested not a one lacks the knowledge of any of these four colors" (Magnus, 1880: p. 6, as trans. in Berlin and Kay, 1969: p. 141). Magnus did find widespread *lexical* neutralization of green and blue, that is, a single word covering both these colors, as have all subsequent comparative studies of color lexicons.

While nineteenth century and early twentieth century researchers saw differences among vocabularies in an evolutionary perspective (biological and/or cultural), in the second quarter of the twentieth century the tide began to turn against evolutionary explanations of human variation and toward cultural and linguistic relativity. This was especially true in America, in the tradition of the anthropologists and linguists F. Boas, E. Sapir, and B.L. Whorf, although there were precursors in the views of the German romantics, who had tended to associate the *geist* of a people strongly with its language. According to Whorf, "The categories and types that we isolate from the world of phenomena we do not find there because they stare every observer in the face. On the contrary the world is presented in a kaleidoscopic flux of impressions which have to be organized in our minds. This means, largely, by the linguistic system in our minds" (1956: p. 212). Throughout the 1930s and 1940s this view gained increasing prominence and in the 1950s and 1960s achieved virtual hegemony in American anthropology and linguistics, with considerable influence in Britain and elsewhere outside of the US. (Chomskian universalism and nativism were to become influential only at the end of this period.)

The parade example chosen by the mid-century American relativists to make the twin points of semantic arbitrariness and linguistic determinism was the lexicon of color. The most influential introductory linguistics textbook of the period, for example, stated: "There is a continuous gradation of color from one end of the spectrum to the other. Yet an American describing it will list the hues as red, orange, yellow, green, blue, purple, or something of the kind. There is nothing inherent either in the spectrum or the human perception of it which would compel its division in this way" (Gleason, 1961: p. 4). This sweeping conclusion appears to have been based on two small-scale empirical studies of color terminology, whose results have subsequently been interpreted differently, one on the Hanunoo language (Philippines) (Conklin, 1955) and the other a comparison of the color terminologies of languages (Ray, 1953). Despite the paucity of evidence, the idea that different languages divide up the perceptual color space in mutually incomparable ways was widespread at the time, doubtless because it fits so well with the prevailing doctrine of radical cultural and linguistic relativity.

Color Terms as Linguistic Objects

Against this background a study appeared in 1969, which reached exactly contrary conclusions. After examining the color term systems of 98 languages, Berlin and Kay (1969) (B&K) proposed that (1) the differences in color lexicons of the languages of the world could be explained as different combinations of a few landmark colors (which were probably human perceptual universals) and (2) the differences in color lexicons of the world's languages could be arranged in an evolutionary progression. In order to carry out this study, B&K found it necessary to limit the domain of inquiry to the 'basic color terms' (bcts) of the languages being compared. (They examined 20 languages experimentally, using standard color stimuli, and interpreted another 78 reports of color terminologies from the literature based on their formulation of the results of these 20.) As a preliminary to this research, B&K offered what they called a definition of 'basic color term' and much of the subsequent research on the linguistics of color terms has had to do with attacking, defending, revising and evaluating this definition.

The B&K study was not without direct precursors. Lenneberg and Roberts (1956) (L&R) compared the color terms of Zuni monolinguals with those of Zuni–English bilinguals and English monolinguals. After isolating the words whose denotation was to be studied, L&R had each informant indicate on a representative array of 230 color samples the denotation of each color word as well as the color sample which best exemplified the reference of that word. B&K used essentially the same method and the same stimulus array as L&R (except for adding black, white, and shades of gray) with the exception that the color words whose denotation was to be studied were selected differently by L&R and by B&K. L&R proceeded by getting speakers to list as many color words as they could think of without color stimuli present, which produced a list of 52 terms. They also elicited lists of color words by asking for names for 24 selected color stimuli, producing a list of 105 terms. The color terms for which L&R show mappings are those most frequently elicited by the second method. L&R show mappings for seven color terms for Zuni monolinguals, corresponding closely to English pink, red, brown, yellow–orange, green, blue, and purple (recall they had no white, black, or gray stimuli). They show mappings for eight color terms for Zuni bilinguals, adding a term for orange, 'olechin-anne' ('orangelike' < English 'orange' + 'anne' 'like') and retracting the area of yellow accordingly. They show 10 mappings for English color terms (pink, red, orange, brown, yellow, green, light green, blue, light blue, purple). No terms like greenish, blue–green, or crimson were mapped, but light green and light blue were apparently ruled in by naming frequency considerations. (L&R's text is not explicit on this point.) Clearly in L&R, as in Conklin's, Ray's, and other early investigations of color word systems some tacit, if hazy, notion of major color term or principal color term is at work. It was this tacit notion that B&K tried to operationalize in their 'definition' of bct.

B&K's Definition of bct

B&K offered what they unfortunately called a definition of bct. Their intent was not to postulate and define a new theoretical entity but to operationalize, insofar as possible, a tacit concept that was already in general use. The guiding intuition of the B&K 'definition' of bct was that each language has a small set of simplex lexemes (or word *senses*, as in the case of English 'green (color)' and 'orange (color)') of pure color meaning (i.e., unlike words such as 'blond'), which collectively name all the color sensations. The bcts are the members of that set. However, B&K stated the definition in terms of eight criteria,

four primary and four subsidiary, the latter to be used in cases where application of the former is not sufficient to decide the bcts of a language. The four primary criteria for a bct were that it (1) be monolexemic (its meaning not predictable from the meanings of its parts, eliminating 'greenish,' etc.), (2) not be a hyponym (eliminating, e.g., 'crimson'), (3) be predictable of any kind of object (eliminating, e.g., 'blond'), and (4) be 'psychologically salient' (eliminating e.g., 'puce' and 'like the neck feathers of a male mallard duck'). Two telling criticisms that have been leveled against the fourth criterion are (1) that it is not a linguistic criterion, while the other three are and (2) that 'psychological salience' is neither a conceptually limpid nor a readily measurable notion. The four subsidiary criteria, designed for use in *ceteris paribus* situations, were that a questionable term (1) have a morphological distribution similar to that of the established bcts, (2) not be the name of a kind of object (which would eliminate English 'orange' if subsidiary criteria were allowed to override primary criteria), (3) not be a recent borrowing from another language, and (4) not be morphologically complex. The B&K definition of bct has led both to practical problems in determining the bcts of a language and to conceptual and theoretical problems regarding the semantics of color in natural languages.

Practical Problems with the B&K Definition of bct

The main practical problem in applying the B&K criteria to given languages is that since language change is always gradual there are many transitional cases. For example, there are many languages with bcts for black, white, red, yellow, and 'grue,' i.e., a single word covering green and blue. There are also many languages with bcts for black, white, red, yellow, green, and blue. When a language changes from the first type to the second type, it is not the case that everyone goes to bed Sunday night speaking the 'grue' language and gets up Monday morning speaking the 'green' versus 'blue' language. Many kinds of in-between situations arise that make it difficult to say which words of the language naming part or the entire green/blue region of color space are bcts. Moreover, there is virtually always widespread interspeaker variation in such cases, complicating further the task of deciding the bcts of 'the language' (*see* Sociolinguistics). Second, the four primary criteria of B&K do not always correlate and the definition gives no clue as to how the different criteria should be weighted in such cases. Also, as mentioned, cultural salience is not a straightforwardly observable characteristic. Workers who have taken the B&K 'definition' as a recipe rather than a heuristic have complained of problems in application in particular cases. Usually, however, these problem cases have involved a single term or a single area of the color space, indicating that the area is one undergoing change.

A third practical issue has arisen in connection with the first B&K criterion of nonpredictability of meaning of a bct from the meaning of its parts. It has been noted that in several Oceanic and Australian languages many of the presumably bcts are in fact reduplicated forms of roots that denote objects notoriously exhibiting the corresponding color. For example, in Yélîdnye (Rossel Island, Melanesia (Non-Austronesian)), the word for white *kpaaîkpaapî* represents reduplication of the nominal root *kpaapî* denoting a pure white cockatoo species. A similar situation holds for the black and red words, the only other plausible candidates for bcts in this language (Levinson, 2000). The question arises whether *Yélîdnye*, and similar languages, can be said to have any bcts at all. The answer is yes. The criterion of nonpredictability of meaning requires not only that from knowing the rest of the *Yélîdnye* language – including the word *kpaapî* and the pattern of reduplication which yields a salient attribute of the denotatum of a noun from reduplication of the noun stem – one could as a *listener* guess the meaning of *kpaapîkpaaî*, but also that as a *speaker* one would know an advance that *kpaapîkpaaî* was the way to express the idea of white. The latter of course would not be possible without memorizing this particular fact, because not all attributive words are formed by reduplication and even if they were the meaning 'white' might be based on some other object or substance.

Theoretical Issues Concerning the B&K Definition of bct

It has been argued, principally by John Lucy (e.g., Lucy, 1997), that a set of bcts isolated by B&K or associated researchers does not correspond to any linguistically legitimate system because there is no insistence in the B&K tradition of research that the set of bcts for a given language be definable by strictly formal, distributional criteria. This critique of the bct concept and practice is based on the questionable assumption that all morphosyntactic categories correspond to semantic categories and vice versa (see Kay, 1999). Moreover, careful empirical studies have shown that application either of the explicit B&K criteria or of the underlying intuition of a small set of linguistically simplex lexemes jointly exhaustive of the color domain can isolate sets of bcts which obviously form a coherent semantic system and whose members belong to several different form classes (see, for example, Maffi, 1990 on Somali). It has also frequently been found that morphological category, including native versus borrowed origin, can correlate with the evolutionary sequence posited by B&K ({black, white} > {red} > {yellow, green} > {blue} > {other}). The Somali case is again illustrative: the words for black, white, and red are intransitive verbs, the words for yellow and green are denominal adjectives and the word for blue (*buluug*), also a bct, is a noun. To say that something is blue, one has to say that it 'has' blue (Maffi, 1990). Such neat correlations between morphology and evolutionary status are, however, sporadic.

Recently, the question has arisen whether all languages do in fact have a small set of lexemes whose denotations are restricted to color sensations and which jointly name all the color sensations. That is, does every language have a full set of bcts? This idea has been dubbed the Emergence Hypothesis. (The question was first raised in unpublished work by Luisa Maffi. See also Lyons, 1995, 1999; Kay, 1999; Levinson, 2000; Kay and Maffi, 2000.) Research on this hypothesis has just begun but it appears that a small fraction of the world's languages may lack complete lexical partitions of the color domain (Levinson, 2000; Kay and Maffi, 2000). Preceding, and in some cases overlapping temporally, with the evolution of bct systems there may exist an evolution toward bct systems.

Nonbasic Color Terms and Noncolor Meanings of Color Terms

The vast majority of studies of color terms, especially since the early 1970s, have restricted themselves to the basic or major color terms, considering nonmajor terms only with a view to excluding them from further consideration. The L&R study described above typifies this practice. There have, however, been studies covering all the lexicalized color expressions of a language, a classic example being Andrés (1949) study of Latin color terms and a more recent example being Bricker's (1999) study of productive and semiproductive morphological process in the formation of secondary color words in two Mayan languages. Bricker also provides a thorough analysis of the noncolor aspects of meaning of Mayan nonbasic color terms, often involving texture and other aspects of surface appearance. Color words frequently also display metaphorical associations to moral, emotional, supernatural, and other kinds of nonphysical entities and beliefs. Such associations have been widely reported in the ethnographic literature.

Commemoration

Barry Schwartz, University of Georgia, Athens, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Commemoration employs narratives, icons, music, monuments, shrines, naming conventions, and ritual observances to awaken ideas and feelings about those parts of the past that embody current ideals. Two categories of commemoration are distinguishable. Positive commemoration, the traditional mode of marking past events and persons, transmits images that affirm society's ideals and grand achievements. Negative commemoration, the marking of events weighing on the present as sources of shame and dishonor, became conventional during the late twentieth-century human rights movement. The early twenty-first century is thus distinctive in its commemoration of guilt and victimhood. To explain these developments, the theories of the 'politics of memory' and 'memory as a cultural system' are invoked.

Commemoration refers to the mobilization of symbols to awaken and preserve beliefs and feelings about the past. The word commemoration derives from Latin (com – together + memorare – to remember: to remember together). Remembering together occurs in every sphere of life – family, association, occupation, community, and society – but its dynamics are most visible in the most inclusive, societal, sphere. Commemoration is society's moral memory, distinguishing events its members believe to be deserving of remembrance from those deserving of being merely recorded. Commemoration promotes society's sense of itself as it affirms its members' mutual affinity and common identification with its past.

Commemorative Symbolism

The primary vehicles of commemoration include written and oral hagiography, icons, music, monuments, shrines, relics, naming conventions, and ritual observances. These 'cultural objects' (Griswold, 1987) lift from the historical record those events that represent a given collectivity's conception of its highest ideals and lowest misdeeds.

Commemorative writing includes biographies, eulogies, poems, plays, and commentaries motivated by admiration or enmity. Emphasizing the moral rather than factual aspects of the past, commemorative texts tend toward hagiography or condemnation and are thus distinguishable from analytic history and chronicling. The line between commemoration and analytic history blurs, however, when the latter is written and published with a view to marking the anniversary of the event or person, which is its subject. First-century Christian lectors read to illiterate Christian communities written accounts of Jesus' life during their Sabbath observances. Newspapers played the major role in the anniversary of Hurricane Katrina (Robinson, 2009).

Music, consisting of anthems, hymns, and inspirational songs, aligns melodic and harmonic structures and lyrics to historical events in such a way as to dramatize their significance. National anthems, school, and military songs are cases in point.

Icons, signs resembling what they represent, commemorate the past by bringing it to visual presence through paintings, statues, prints, photographs, motion picture film, television, and online video.

Monuments, including obelisks, antique temples, and other memorial structures, are designed to elevate the public imagination by dramatic reference to both grand events and atrocities.

Shrines, such as birthplaces, residences, state buildings, military headquarters, battlefields, cemeteries, and places of surrender, execution, and extermination – all play a key role in commemoration because they bring the individual into direct contact with sacred sites. Shrines are sacred because they are, by definition, 'containers' (Latin, scrinium – case, chest) of relics. In contrast to mundane things, relics are physical objects associated with extraordinary events or used by extraordinary people.

Naming patterns make past events ubiquitous by incorporating their memory into the identity of businesses, streets, cities, towns, counties, states, rivers, and mountains.

Observances (periodic performance of anniversary, centennial, and holiday rites) have been analyzed more extensively than other commemorative forms, but their functions are the same: to maintain the vitality of the past, to prevent it from being forgotten and to preserve what is essential to the collective consciousness.

Commemoration's observances, together with its other media, comprise a sign system recommending selected historical events for contemplation, promoting a common legacy by making them tangible and accessible to all.

Commemoration, History, and Collective Memory

Commemoration, history, and collective memory perform interrelated functions. Memory is a necessary property of the mind, a fundamental component of culture, and an essential aspect of tradition. Although individuals alone possess the capacity to remember the past, they never do so singly; they do so with and against others situated in different groups and through the knowledge and symbols that predecessors and contemporaries transmit to them.

A variant of collective opinion, collective memory refers to the *distribution* throughout society of what individuals believe, feel, and know about the past, how they judge the past morally, how closely they identify with it, and how much they are

inspired by it as a model for their present conduct. The word 'distribution' is emphasized because its key property is variation, which denies the possibility of consensus. That every distribution also has a central tendency makes total dissensus equally impossible. Because similar memories appear in comparable groups of individuals widely dispersed and unknown to one another, and because these memories replicate themselves across generations they must be treated as emergent, objective entities that stabilize and link the consciousness of present and past.

History, as French sociologist Maurice Halbwachs (1980 [1950]) defined it, seeks an objective standpoint to assess the causes and consequences of events. It is 'situated external to and above groups' and describes the past independently of contemporary opinions and conditions. Once established, Halbwachs believed, historical knowledge remains stable – its stream of facts and demarcations 'fixed once and for all.' In contrast, commemoration and collective memory remain significant only as long as they remain relevant (pp. 80–81). Pierre Nora, a French historian, explicitly adopts Halbwachs' belief in the fundamental opposition between history and memory, and he regards all commemorative forms as *lieux de memoire* (sites of memory), that is, feeble efforts to defend against the relentless disenchantment of analytic history.

History's goal is, thus, to rationalize the past; commemoration and its sites, to sanctify it. History makes the past an object of analysis; commemoration, an object of commitment. History is a system of 'referential symbols' representing known facts and their sequence; commemoration is a system of 'condensation symbols' (Sapir, 1930: pp. 492–493) that simplify events of the past and clarify the moral sentiments they inspire. History, like science, investigates the world by producing models of its permanence and change; commemoration, like ideology, seeks to promote commitment to the world by producing symbols of its values and aspirations (Geertz, 1973: pp. 193–233).

Contrasts among history, commemoration, and memory must not be exaggerated. James Dunn (2003), prominent among historical Jesus scholars, declares that 'the quest for the historical Jesus' can only be a quest for the 'Jesus remembered' by contemporaries and successors who heard or wrote about him (p. 335). Dunn's statement stands out in the context of successful efforts, beginning in the first decade of the twenty-first century, to integrate collective memory, commemoration, and biblical studies (Kirk and Thatcher, 2005).

Commemorative Networks

When commemorative symbols are combined, they convey meanings that differ from those borne by any one symbolic object. To activate the commemorative process through story, monument, song, icon, ceremonial observance, or other signs, therefore, is to activate memories that include but extend beyond the persons and events commemorated. The significance of historical figures and events also change as they are placed in commemorative networks composed of objects absent in previous networks. Thus, Jefferson Davis was sworn in as president of the new Confederacy in Richmond, Virginia beside a massive equestrian statue of George Washington, which was itself adopted as the Confederacy's emblem. During the Civil War, Abraham Lincoln ordered large-scale offensive operations on Washington's Birthday. Upon death, scores of mourning prints placed him in the company of Washington. During the Progressive Era, visual images of Abraham Lincoln were paired with contemporary figures, including President Theodore Roosevelt, identifying Lincoln as one who would have supported Progressive Era reforms. The pairing processes fanned out broadly not only within a network of people whose prestige enhanced and was enhanced by Lincoln's but also to networks of events and structures – notably, political and economic reforms and relentless condemnation of plutocracy. In such mnemonic webs, existing beliefs about Lincoln were reorganized, their institutional roots deepened, and a new and autonomous collection of beliefs about him accumulated. Common features of people and events with which Lincoln was symbolically connected were generalized to Lincoln himself. In this way, he changed through the late nineteenth century from a symbol of national unity to a symbol of social and economic reform.

Commemoration, as Abraham Lincoln's case suggests, is a structuring process that partially overrides the qualities of its objects and imposes upon them its own pattern. Commemoration is creative because it fills in what is lacking in its objects, whether historical figures or events, by attributing to them the features of people and events that a given community deems similar (and other communities deem offensively dissimilar).

Memory of Commemoration

Commemorative symbols represent both the events they commemorate and the concerns of those creating them. Because commemorative symbols refer to the memory of their own genre, they exhibit traces of the way events presently commemorated have been recognized previously. In other words, commemorations are 'path dependent' – shaped by their development as well as their referents; they express an ongoing process of meaning making. Jeffrey Olick's (2007) analyses of discourses marking historical regret, including the memory of National Socialism in Germany, demonstrate this point persuasively. Not only are present commemorations modeled on past commemorations; the *style* of these earlier commemorations, as Andrea Cossu's (2011) study of Italian antifascist representation shows, are themselves path dependent and therefore essential to reinforcing the memory of commemoration and the understanding of how it works.

The redundant, cyclical features of path dependency are exemplified in the holiday calendar. In the United States, the annual repetition of Martin Luther King Day, Lincoln's Birthday, Washington's Birthday, Memorial Day, July Fourth, Columbus Day, Veterans Day (formerly Armistice Day), Pearl Harbor Day, in that order, enables the single individual to experience, year after year, although with demonstrably decreasing enthusiasm and solemnity, the representation of major events in his nation's history.

Path dependency can negate rather than reaffirm earlier commemorative objects. Conceived in light of their generic predecessors, certain war memorials, in certain social circles, evoke more criticism than approval. The establishment of

a Korean War Veterans Memorial, supervised by a committee hostile to the Vietnam Veterans Memorial's antiwar inspiration, set down firm requirements in its invitation to design competitors (Schwartz and Bayma, 1999). The Korean Memorial had to be visible, uplifting, expressing honor, pride, and dignity, evoking admiration and gratitude. It had to be visible rather than set below ground level, as is the Vietnam Memorial, whose original plan expressly excluded patriotic symbolism. The Korean War Memorial's design is shaped as much by its negative Vietnam War predecessor as by the actual war it commemorates.

Commemoration in the Post-Heroic Era

Commemoration sites are viewed, witnessed, or attended with solemnity by some; ignored, regarded with indifference, or even ridiculed by others. During the Enlightenment, commemoration began to lose its capacity to instruct and inspire, but this trend assumed its sharpest downward turn during the last third of the twentieth century, strongly evidenced in the United States by multiple indicators, including site visitation statistics and national surveys of historical figures' diminishing renown. As the public's interest in its history fades, however, its commemoration ceases to be taken for granted and scholarly interest therefore escalates. In the *Dissertation Abstracts*, with commemoration the keyword and Masters and PhD theses included, two entries are found between 1970 and 1979, 6 and 17 entries during the 1980s and 1990s, respectively. During the first decade of the twenty-first century, 53 entries appeared. In *JSTOR*, an online journal archive, the very same trend appears. Academic interest in commemoration increases exponentially at the turn of the twenty-first century as the heroic past fades from the collective consciousness and becomes an object for dissection rather than adoration.

Until the last third of the twentieth century, references to the anniversary of significant events, such as George Washington's birth, filled local newspapers' front pages with editorials, commentaries, ink drawings, stories about different parts of his life, including schedules where civic organizations, from trade to professional organizations and churches, held their programs. Schools gave special lessons and ceremonies the day before Washington's Birthday, when all federal and most state and municipal activities were suspended. Presently, the commemoration of his birth consists mainly of brief remarks about his life in newspapers and television commentary. In contrast, the anniversary of Martin Luther King's January birth is widely recognized, with an increasing number of streets and organizations annually named for him and more printed space and television time devoted to him. These rites are consolidated during the entire month of February, federally recognized in 2008 as Black History Month, succeeding Negro History Week, begun in 1926.

The present 'Era of Commemoration' largely perpetuates the memory of victims of injustice, despised minorities, and oppressed people. 'The explosion of minority memoriesm,' according to Pierre Nora (2002), has changed commemoration's cultural function. "Swayed by the democratization of history," it has come to resemble a protest movement, a "revenge of the underdog… ."

The superimposition of sites of regret upon sites of triumph is now the keystone of many national commemorations. Writing about Grozny's monument to the Soviet Union's wartime deportation of Chechnyans, Brian Williams (2000) declares: "One must know a nation's tragedies and the way they commemorate them to know its soul" (p. 128). Tragedy, not triumph, he says, defines national memory. But the two are often indistinguishable. Villainy and heroism, the mundane and the epic, events worth forgetting and those worth preserving – it is the blurring of these lines that goes to the core of the postmodern condition. The transition from a pre–World War II culture of commemoration stressing heroic achievement to a postwar culture stressing oppression, trauma, victimhood, and injustice is widely evident. In his observations on the commemoration of French resistance against Nazi occupiers, Nathan Bracher (2007) declares that the general evolution of European sensibilities is driven by disinterest, if not disdain, for warrior virtues, and a newfound appreciation of warriors' victims. Europe as a whole is now united by rejection of war, intolerance, and inequality – all dramatized by its use of the Holocaust narrative as a more or less de-Judaized symbol of human rights. France, for example, commemorates often the victims of the occupation; rarely the valor of the resistance. The memorial to militant resisters, located at Mount Valerian, site of more than 1000 resister executions, bears no mention of their successes against the strong enemy with whom most Frenchmen passively cooperated. It implies reluctance to commemorate French men and women as slayers rather than victims of their Nazi rulers.

Commemorating historical wrongdoing became commonplace during the late twentieth century in connection with the emerging 'human rights movement.' The new 'politics of recognition' also bends the commemorative impulse to achievements and sufferings of communities previously marginalized and underrepresented in the historical record. These sites of regret are more likely to be found among 'cultures of dignity,' dedicated to the cultivation of democracy and individual rights, than among 'cultures of honor' dedicated to the cultivation of individual obligations to the nation, state, or community. The creation by the American government of the United States Holocaust Memorial, to take but one instance, justifies itself, as do European memorials, on the ground of a universal moral relevance transcending the suffering of European Jewry. Doing so, the Memorial erodes the Holocaust's particularistic relevance (Rabinbach, 1997) by ignoring the link between genocide and Jewish history. The same rationale applies to museums of Native American, African-American, Asian-American, and Hispanic-American experience. The commemoration of helplessness is even evident in the design of heroic monuments. Franklin D. Roosevelt was leader of the free world during its most severe economic and military challenges, but his memorial recognizes Americans' affection for handicap by placing on the site a statue of the paralyzed president in his wheelchair. Likewise, Dwight D. Eisenhower's Memorial, as presently planned, deliberately qualifies his military and presidential achievements by representing him as a barefoot boy in Kansas.

Diversity, another aspect of post-heroic commemoration, distinguishes the Korean War Veterans Memorial, which includes a wall divided into slanted vertical and straight horizontal lines, the resulting cells of which represent each of the

military services. Within each service, different branches of activity, and within each branch of activity different racial, ethnic, and gender groups, are recognized. For example, engineering, armor, infantry, artillery, and medical units are represented by men and women of all racial and visibly ethnic groups. The 19 statues of infantrymen, too, are meant to be recognizable as European-American, African-American, Asian-American, and Hispanic-American. A war memorial conceived to honor sacrifice for the sake of a transcendent nation ironically takes a pluralistic turn and, by so doing, commemorates equally the separate communities of which that nation is composed. Commemorative pluralism, in this precise respect, articulates the mundane segments, rather than the transcendence, of the nation-state.

Anomalous Commemoration

Diversification of the commemorative process admits of anomalous sites. Anomalous commemoration combines aspects of the past conventionally deemed morally incompatible, such as President Ronald Reagan's (1985) visit to Germany's Bitburg military cemetery, where the remains of Wehrmacht and SS personnel are buried, on the same day as his visit to the Bergen-Belsen concentration camp site. Tokyo's Yasukuni Shrine, likewise, commemorates the souls of convicted and executed war criminals as well as the innocent who died for their country, which is why Prime Minister Junichiro Koizumi's public visits to the shrine set off indignant protests abroad, especially in Korea and China, and, at home, a torrent of controversy that has yet to abate (Mochizuki, 2010). In the United States exists a similar incongruity: monuments to Confederate leaders and soldiers who defended slavery are accompanied in Richmond, Virginia, the Confederacy's capital, by a statue of The Great Emancipator, Abraham Lincoln, and his son overlooking the former Tredegar weapons factory. The Vicksburg, Mississippi statue of Lincoln in the friendly presence of Confederate President, Jefferson Davis, is another instance of anomalous commemorative pairing. In Bitburg, Tokyo, and Richmond, those considered virtuous and villainous are commemorated together.

Monuments to executed military deserters are equally striking. Once the embodiment of disloyalty and cowardice, desertion is now defined as a symptom of stress or battle fatigue. The Shot at Dawn Memorial in Staffordshire, England, dedicated in 2001, consists of the statue of an executed 17-year-old surrounded by 306 stakes to which British and Commonwealth soldiers were tied and executed during World War I. A single stake, also dedicated in 2001, commemorates English, French, and Belgian soldiers executed in Ypres, Belgium. French President Nicholas Sarkozy spoke at the Duaumont Fort, France, site of the Battle of Verdun, announcing that those executed were 'men like us' who deserved to be remembered because they had 'reached their extreme limits.' Germany commemorates more deserters than any other country. In Kassel, Hannover, Ulm, Cologne, Stuttgart, and other cities stand monuments recognizing the men executed during World War II by the German military.

Commemoration is no less anomalous when its intensity is disproportionate to the significance of its object. The apotheosis of Rosa Parks included public memorial services in three cities, including Washington, DC, where she laid in state in the US. Capitol Rotunda under a flag flying half-mast while a plan was inaugurated to place her statue in the Capitol Rotunda. Her celebrity occasioned the forgetting of others who risked and accomplished more, far more, than she (Schwartz, 2009).

Surface Commemoration

The 'death dip,' which refers to lowered mortality rates among the intensely religious on days leading up to their major holidays, followed by the steep increase in rates when the holiday is over, is a measure of commemoration's role in the life of the individual. This effect is variable. To find a death dip among orthodox Christians prior to Christmas and Easter, and among orthodox Jews prior to Rosh Hashana and Yom Kippur is unsurprising; to find it related to such American holidays as Presidents' Day, whose object is ambiguous, would be shocking.

The Monday Holiday Act presupposes the weakened state of the national consciousness by moving holidays that fall in the middle of the week to Mondays with an explicit view to promoting more tourism, shopping, travel (and fuel use) by automobiles and public carriers over long weekends. Presidents' Day is the new name for George Washington's Birthday, the only president on the federal holiday calendar. Absent from this calendar but now on most state calendars, Presidents' Day commemorates different people: here, George Washington; there Abraham Lincoln; elsewhere, Washington and Lincoln; somewhere else, all presidents; in another place, Abraham Lincoln and Daisy Bates. The casualness with which Presidents' Day is recognized embodies Amitai Etzioni's (2001) claim that as 'recommitment holidays' have declined in relevance, 'tension management' holidays, including New Years Day, Halloween, and Valentine's Day, have become more widely celebrated. Tension management holidays are said to perform a 'safety valve' function: they contribute to reducing tension accumulated through the normal difficulties of life. Presidents' Day is one of these holidays. Most importantly, certain recommitment holidays have been converted into holidays of tension release. Memorial Day and July Fourth, observed with almost religious passion a century ago, are still federal holidays but observed with relatively little ritual and even less fervor. They provide more opportunity for recreation than commemoration.

To be severed from the past is no longer to be identified with it. Michel-Rolph Trouillot (2000), for example, explains that national apologies and rituals of regret for past offenses are superficial because their participants, representatives of aggressors and victims, have no organic connection to the communities they represent. Commemoration is only skin-deep when it preserves but fails to instruct and inspire, when its participants recognize forebears as benefactors but no longer feel themselves to be beneficiaries, when earlier sacrifices, even those made explicitly for the benefit of posterity, fail to evoke gratitude, when the past is remembered but unfelt and unjudged.

The death of living faith is not contradicted by recent surges of national enthusiasm. Ritual displays accompanying the 1991 Gulf War, 9/11, and enthusiasm at the start of the Iraq War show that nationalist sentiment, which generally exists in

a latent state, is a powerful source of social energy during crises. Yet, the ends for which such energy is expended exist in the national present; they recognize but draw little inspiration from the national past.

Transitory Commemoration

Some commemorative structures, although inspired by deep sentiment, are impermanent. They consist of easily removable objects that express feelings (usually regret) over a (usually recent) loss or calamity. Immediately after 9/11, people across the country set up memorial candles in memory of the thousands killed. As the shock wore off, the sites were vacated. Often, religious markers are placed at the site of a fatal automobile accident, but most are recognized by only a few drivers before the elements destroy them. Some temporary sites assume conspicuous dimensions. After Princess Diana's death, an enormous mound of flowers appeared at the gate of Buckingham Palace, but on the first anniversary of her death the Palace gate was conspicuously vacant. The 2005 London Subway Bombing, too, led to a fleeting, media-driven commemoration but no physical monuments (Hoskins, 2011).

In some places, the permanent and transitory coexist. At the Vietnam Veterans Memorial, the aggrieved place personal objects beneath the name of the lost. Gathered up by the US. Park Service and stored, these items are selectively displayed in a remote museum, giving them at least a probability of permanence they would otherwise lack.

Aborted Commemoration

'To abort' is an infinitive denoting the act of preventing an activity from completing itself. Among the best known of aborted commemorations is that of the Smithonian Museum's (1995) Enola Gay exhibit that was intended to depict the consequences of the nuclear attack on Hiroshima and Nagasaki. The exhibit's undertone, critical of the bomb's use and deftly criticizing the United States for excessive force, despite the 1000 *daily* American casualties at sea during the weeks prior to Hiroshima, disturbed many influential persons and associations. Congress withheld funding, and the exhibit was canceled. So, too, organizers of the International Freedom Center planned to use the Ground Zero site to redefine 9/11 as one of a long line of atrocities throughout human history, including American slavery, the mistreatment of native Americans, Japanese Americans, and poverty. New York's political representatives perceived the Freedom Center a 'blame America first' project; others interpreted its plans as an effort to mute 9/11 by commemorating victims who had no relation to it. Despite its many supporters, including the influential *New York Times*, Governor George Pataki declared the museum an anti-American platform at worst; at best, an inappropriate site for ideological expression, and he refused to approve it.

The logic framing The Freedom Center's proposal and rejection is also manifest in efforts within the nation of Israel to commemorate the *Nakba* (Catastrophe), namely, the establishment of the state of Israel. Almost all Arab-Israelis, including their *Knesset* (Parliament) representatives, commemorate this day with expressions of grief, but the idea is not only debated but endorsed within leftist Jewish institutions. The most enthusiastic supporters are, in fact, urging their society to mourn its success at preventing its own destruction. In addition, editorial headlines in Israel's left-leaning *Ha'aretz* endorse efforts to change the lyrics of the national anthem and the design of its flag to make them acceptable to Israeli-Arabs. Although reenergized within many Jewish and Muslim organizations, the movement to commemorate the Nakba's anniversary is vigorously rejected by the Israeli mainstream.

Delayed Commemoration

Construction of some commemorative sites are unduly delayed rather than aborted. Throughout World War II, American and British magazines honored Air Chief Marshall Arthur (Bomber) Harris by placing his photograph on their front cover. He had avenged the Blitz many times over by attacks on German cities. Almost 50 years passed before a statue of Harris was officially approved. England's left had always viewed the ferocity of Harris's raids as disproportional to the damage and death caused by the Luftwaffe. Indeed, activists vandalized the statue shortly after its London unveiling. In this connection, 67 years passed before public subscriptions paid for an official memorial to the RAF Bomber Command, which lost 55 000 men in the air war against Germany. All the social and economic problems associated with recovery from war make delayed commemoration the rule rather than the exception, but opposition to Bomber Harris and his air crews could have only arisen on a mass scale in the late twentieth century, when obsession with human rights transformed German populations supporting Nazi war factories into helpless victims of overwhelming force; the British airmen, brutes deserving no place in posterity. Allies used that same 'disproportionate force' to drive the Nazis out of France – a heroic act at the time but one that now violates the moral sensibilities of French textbook writers as much as it disturbs the humanitarian conscience of many English and American intellectuals.

Theories of Commemoration

The common feature of current commemoration theories is their strong although not exclusive emphasis on minorities and victims, but each takes up a different facet of the problem. Hegemony theory, multiculturalism, postmodernism, and critical theory give insight into the political motives that commemorative objects embody. By contrast, the cultural lens focuses on why creators design such objects as they do and what they mean to viewers and listeners. The theories also differ on what commemoration is: whether a process of construction or retrieval, a mirror reflecting the concerns and interests within a society or a lamp of inspiration and moral precedent.

The Politics of Commemoration

In the first strand of the politics of commemoration, power is concentrated and expresses the tastes, values, and interests of

society's elite. Elite producers of commemorative symbolism bring the past to life as they manipulate the attitudes of their audience in their own interest (Gillis, 1994). Despite efforts to universalize this model, it is most applicable to authoritarian societies wherein 'memory laws' (Koposov, 2011) sustain the official version of history. The premise of the second strand of the politics of memory is that power is diffused and that commemorative objects emerge from a matrix of cross-cutting coalitions, networks, and enterprises rather than a ruling elite's interest in maintaining its privilege. The fate of artistic and presidential reputations, Holocaust memories, monument making, place naming, and the organization of museums exemplify commemoration as a pluralistic network of interest and power. John Bodnar's (1992) distinction between 'official' and 'vernacular memory' is an instance of the pluralistic mode, as is Lorraine Ryan's (2011) conception of resistance as a necessary component of memory. Monopolies on memory and commemoration are, thus, difficult to establish because competing interpretations are inevitable, and free societies allow, indeed, encourage, their expression.

The politics of commemoration are also evident in 'counter-monuments.' The Korean War Veterans Memorial was expressly conceived to counter the design of the nearby Vietnam Veterans Memorial. An even more radical instance of counter-monuments is based on James Young's conviction that commemoration is a substitute for memory and cuts off the people from a real appreciation of their past. Open-ended debate over the meaning of an event, Young asserts, is the ultimate counter-monument (374).

Shortly after the assassination of Israeli Prime Minister Yitzhak Rabin, admirers constructed a monument near the spot where a right-wing zealot assassinated him. For many years, Rabin admirers, mainly liberal, assembled at the monument every Friday to hear speeches and music in remembrance of his life. No such assembly and no such monument exist in the conservative city of Jerusalem (Vinitzky-Seroussi, 2009).

Political ideology also influences commemoration at the aesthetic level. Cultural conservatives tend to favor 'triumphal' commemorative sites, exemplified by the Washington Monument, Lincoln Memorial, Mount Rushmore, the Iwo Jima Memorial – sites that affirm patriotism and the virtues of the nation-state and its leaders. In contrast, liberals tend to reject traditional commemorative forms. Massive monuments, imposing statues, long and noisy parades, among other ostentatious displays are sources of disfavor. The political left, however, commemorates its favored groups by this very same aesthetic. Leftist critics consider Washington's World War II Memorial to be 'fascist' and condemn it artistically because its gothic design fails to conform to the existing Mall monuments. They raise no such objections against the Native American museum, located near the Capitol Building but colored yellow to give the appearance of a huge adobe structure. Nor do they criticize the massive Martin Luther King monument, designed by a sculptor from the People's Republic of China, representing the great peace leader in the same genre as that commemorating Kim Il Sung in North Korea and Mao Zedong in China. Visitors look up to see an enormous Martin Luther King stepping out of an enormous granite block.

Subordinating memory to political power, the politics of memory falls short in three respects. First, in the United States and Europe, no institution does more to commemorate its past wrongdoings than the state. Second, given that all commemoration requires political authority to make it effective, the question of why national and local elites choose to commemorate some persons and events and not others remains unanswered. Third, ideology often trumps politics in determining why the public accepts some elite efforts and rejects others.

Commemoration as a Cultural System

Most commemorative events involve political ideals, sentiments, and judgments, but they are rarely efforts to gain political advantage. The roots of commemorative conflict run too deep for such a simplistic account. In Michael Schudson's (1992) words, "Examining the past is motivated not only by a drive for legitimation … People seek to know what is right, what is true … They seek some kind of direction when they are aimless. They seek in the past some kind of anchor when they are adrift" (p. 213). In short, commemorative symbols articulate meaning, not power.

Conceived as a source of meaning, commemoration is less the construction of a manipulative interest group than a moral frame in terms of which people orient themselves. Commemorative agents, thus, perform more like priests than like manipulators and lobbyists; they seek to reaffirm beliefs they share with rather than impose on their audiences. Commemoration is always a model *of* society – a reflection of its needs, interests, fears, mentality, and aspirations – but it is more importantly a model *for* society – a program defining its values and goals and a frame for organizing the meaning of its members' experience.

As a cultural system, commemoration makes past and present meaningful in terms of one another, which is why the production of commemorative objects becomes most urgent when some significant event is in danger of being forgotten – a situation to which Jan Assmann's concept of *Traditionsbruch* (tradition break) refers. Assmann introduced the *Traditionsbruch* concept during the 1990s, but it was rapidly assimilated into the field of biblical studies during the first decade of the twenty-first century (Kirk and Thatcher, 2005; Thatcher, 2008). Thus situated, it demonstrates the limits of 'communicative memory' (including oral tradition) and explains why the first written gospel appeared when it did. As the generation that lives through a particularly significant event dies out, those intent on preserving knowledge of it begin to write, paint, sculpt, build monuments, and organize observances. In particular, the first Gospel was written 40 years after the death of Jesus, when the last of his contemporaries were still able to tell each other what they knew about him. Likewise, questions of guilt and identity on the British islands of Guernsey and Jersey, whose citizens cooperated with the Nazi occupiers, "became more urgent with the realization that the witnesses of these times would no longer be around" (Carr, 2012: p. 53). Just so, the Korean War and World War II Memorials were rushed to completion as those who deserved recognition for serving in these wars were on the verge of vanishing. Each case reflects society's fear of the *Traditionsbruch* – the rupture that erodes irretrievably the present generation's knowledge of its forebears.

Society's fear is justifiable, for symbol systems are mutable. The generation that ascribes the same meaning to commemorative objects as did its forebears is theoretically impossible, for doing so would require a society to be so fixed as to clone itself culturally. Commemorative transformations are always superimposed upon commemorative continuities, and they can be dramatic. The destruction of King George's statue by rebelling Americans colonists in 1776; the deterioration and defacing of countless Civil War monuments throughout the United States, and the late twentieth-century vandalizing of images of sacred figures are simple examples. More complex is the development in Dublin of the Irish National Memorial to honor 300 000 Irishmen who fought with the English during World War I (Rigney, 2008). The Memorial's plan was drafted in 1919, implemented during the 1930s, but interrupted by World War II and Irish neutrality. After the war, the eroded monument was restored and formally dedicated in 1988 as England and Southern Ireland reconciled. Such are the vicissitudes of commemorative objects and of the mentalities they articulate.

Commemorative symbols gain and lose relevance and resonance independently of the distribution of power, but power or, for that matter, any social or economic asset, performs significant cultural functions. Brian Conway's *Bloody Sunday* (2010) is one of the best examples of a multiple factor theory of commemoration, defining explicitly its cultural, economic, political, and situational contexts – a 'thick (contextual) description' that roots the concept of commemoration deeply in the social fiber. That Conway's topic consists of victims of oppression rather than agents of victory, however, is what makes it so apt an example of commemoration as a twenty-first century cultural system.

Conclusion

The past's relevance diminished during the late twentieth century in two ways. First, the individual's connection to his or her society and its past was weakened by the discrediting of its metanarratives – its great legends, myths, and histories. Since the key feature of metanarratives is embodied in a plot structure that interprets events in a way that can be widely understood and shared, people require them, collectively and individually, to make sense of experience. 'Of what great story is my life and death a part?' is the question they ask in their effort to define themselves and the meaning of their lives. This question would not be worth asking if the great stories that impressed our forebears still impressed us – and if there were no consequence, no cost, to the repudiation of the greatnesses of history.

As the positive aspects of societal narratives are ignored, the orienting past tense of the individual's life is negated. These positive narratives are not completely ignored, but few would deny that diminished engagement with the past distinguishes recent from remote generations. The adjective 'diminished,' however, must be underscored, for diminishings are more difficult to describe and comprehend than disappearances. At question is whether traditional reverence for the past is destined to disappear or whether it remains because it is not traditional at all but rather a fundamental requirement of societal continuity, because there is a level below which commemorative interest, if not passion, does not fall. Amy Corning and Howard Schuman's (2013) surveys of events as different as 11 September and Woodstock are relevant to this point. As the 10th and 40th anniversaries of these events approached, media coverage grew and more people named them as memorable events. The percentage mentioning these events fell after the mass media ceased coverage, but that percentage remained higher after the coverage than before.

The present situation, then, must be rightly understood: balkanized preferences have enervated the West less politically than culturally. Because the West's mentality is currently progressive, compassionate toward the underdog and skeptical of everyone else, because it is irreverent, pluralistic, relativistic, and less attached to tradition than ever before, it has begun to alienate individuals from whatever historical legacy they possess. In the deliberate minimizing of founders and their ideas, the substitution of shallow pity for the invocation of sacrifice, courage, and perseverance, and the anxious commemorative concessions to even the most outrageous claims of 'oppressed minorities,' there is something at once gained and lost. The West has never been freer of religious, ethnic, and racial hatred; yet, its historians – often justly, frequently unjustly – challenge official accounts of their nations' historical virtues. As democratic peoples adopt the *mea culpa* perspective on history, they lose sight of the great transformations wrought by their forebears; they lose sight of themselves as historical beings, forget that they have inherited their most valuable possessions from those whom they so ardently criticize. Merely to contemplate these issues is to affirm commemoration's ironic functions in twenty-first century society.

Commodity Chains

Elaine R Hartwick, Framingham State University, Framingham, MA, USA

Abstract

Geographically conceived, commodity chains consist of significant production, distribution, and consumption nodes, the spatial connections among these, and the economic, social, cultural, and natural conditions of production and consumption. This concept connects the generation of cultural (signifying and representational) effects at the consumption node of a commodity chain with the social and natural conditions at the production end of the chain, the purpose being to 'bring home' to consumers the consequences of consumption. Formulated in this way commodity chains are said to constitute an analytical basis for a transformative politics and a new platform for understanding global capitalism.

Commodity chains follow specific commodities as they are moved over space from points of production to points of consumption. Commodities are seen as originating in regions of production and moving through networks of economic agents, as with producers, distributors and transporters, to regions of consumption, where they are advertised, retailed and consumed. The commodity chain concept has potential for demonstrating the effects of consumption on labor and the environment. Armed with greater geographical knowledge, organized around the commodity chain concept, consumers can make choices that more fully consider the effects of their consumption on workers and the natural environment.

Conceptions of Commodity Chains

Since the middle 1970s there has been a resurgence of interest in space conceptualized not as a homogenous expanse of territory, but as channels, networks, nodes, and chains of connection. In economic geography the main interest resides in investigating the spatial organization of business networks (Yeung, 1994). While related to this interest, commodity chain analysis differs, in that analysis focuses on commodities, rather than industrial organizations or networks of interfirm relations. The geographical literature contains numerous references to concepts similar to commodity chains. For example, Harvey (1989) implies the notion of a commodity chain in arguing the importance of knowing the effects of consumption on the conditions of production: "We can take our daily breakfast without a thought for the myriad of people who engaged in its production. All traces of exploitation are obliterated in the object." However, the commodity chain concept only began to be used formally in the middle 1980s. There is now a substantial record of case studies (Hughes and Reimer, 2004). Three versions of commodity chain analysis can be discerned: global commodity chains; systems of provision; and commodity circuits. These versions have recently been criticized as limited in scope and applicability, and an expanded commodity chain concept proposed.

Global Commodity Chains

The notion of commodity chains has been developed in the world systems approach mainly in the discipline of sociology (Hopkins and Wallerstein, 1986; Gereffi, 1994; Bair, 2005, 2008). As characterized by the world systems approach, a commodity chain, or value chain, refers to a network of labor and production processes whose end result is a finished commodity (Hopkins and Wallerstein, 1986). Gereffi and his coworkers see interorganizational networks linking households, enterprises, and states to one another within the world economy (Gereffi et al., 1994). Global commodity chains stress the organizational scope of transnational production arrangements: that is, the linkages among economic agents, such as raw material suppliers, factories, traders, and retailers. In this view, commodity chains have three main dimensions: (1) an input–output structure, in the sense of a set of products and services linked together in a sequence of value-adding economic activities; (2) territoriality, as with spatial dispersion or concentration of production and marketing networks; and (3) a governance structure, in terms of authority and power relationships that determine how financial, material, and human resources are allocated and flow within a chain (Gereffi et al., 2005; Cattaneo et al., 2010).

Two distinct types of governance structure are distinguished: producer-driven and buyer-driven commodity chains. In producer-driven commodity chains, transnational corporations or other large integrated industrial enterprises control the production system. In buyer-driven commodity chains, large retailers, brand-named merchandisers, and trading companies set up decentralized production networks in exporting countries, typically in the Third World (Hassler, 2003). The latter pattern of trade-led industrialization is common in labor-intensive, consumer goods industries such as garments, footwear, toys, household goods, consumer electronics, and a wide range of handcrafted items, such as furniture or ornaments. International contracting is generally carried out by independent Third World factories making finished goods, rather than components or parts, under original equipment manufacturer arrangements, and with specifications supplied by the buyers and branded companies that design the goods (Gereffi, 1994; Gereffi and Memedovic, 2003). In these studies firms constitute the main unit of analysis and unequal distributions of wealth along the chain are explained as outcomes of competition and innovation at the level of firms. A third type of governance structure has also been proposed emphasizing the rise of

a financial sphere made up of institutional investors and executives of large corporations commanding the top of global commodity chains (Palpaceur, 2008).

Systems of Provision

A second approach to commodity chain analysis derives from Fine and Leopold's (1993) rejection of horizontal analyses of consumption that stress commodification and aestheticization connected with retailing, and their favoring, instead, of the vertical dimension of the system of provision – the commodity-specific chain connecting production, distribution, marketing, and consumption, and the material culture surrounding these elements. Different systems of provision result from distinct relationships between material and cultural practices spanning the production, distribution, and consumption of goods (Fine and Leopold, 1993). This perspective allows for a more dynamic consideration of consumer behavior in economic transformations within advanced capitalist economies.

Some accounts argue that production is now consumer-driven (Piore and Sabel, 1984), while others emphasize technological change or regulatory institutions in causing economic change (Harvey, 1989). It has been argued that both sets of literature inadequately conceptualize consumption, and that a system of provision approach allows for a more balanced treatment of the relationships between production and consumption (Leslie and Reimer, 1999). Fine and Leopold (1993) also recognize the changing relationships between the symbolic meanings of goods and their physical contents. Thus it is important to trace not only commodity movements over space, but also the discourses and representations operating in systems of provision.

Commodity Circuits

A third approach to commodity chain analysis, tracing commodity circuits, combines work in the political economy tradition with ideas derived from poststructural social theory. The notion of a circuit of culture has been used in examining the ways geographical knowledge of commodity systems is shaped and reshaped and in showing how particular cultural artifacts move through the circuit. Unlike the notion of a chain, circuits have no beginning or end, but instead Cook and Crang (1996) envision dense webs of interactions between all sites, with commodities interrelating with other goods as they travel. Rather than privileging one site, such as production, in interpreting the meaning of a commodity, explanation lies in combining a number of different processes. An appropriate politics of consumption recognizes the fragmentary and contradictory nature of the knowledges through which commodity systems are imagined (Cook and Crang, 1996). Rather than assuming that consumers have little awareness of the quality and geographical origins of commodities, this approach sees commodity circuits constructed and reconstructed through consumer knowledge. This view might be criticized for eventually abandoning the concept of a chain altogether and for neglecting ideas of consumer resistance and activism (Leslie and Reimer, 1999).

Recent Tendencies in Commodity Chain Analysis

Although useful in terms of conceptualizing the connections between firms and actors across space in the production of final outputs, these versions of the commodity chain concept fail to connect the sign of the commodity at the consumption end with labor and the natural environment at the production end. In not following through at the consumption end, world systems theory misses a vital opportunity to connect commodity chains with advertising, popular culture, and the geography of consumption. By not tracing firms' activities back to the conditions of workers, economic geography reduces labor to being yet another input in the overall production process, divorcing economic analysis from the politics of production. By not rooting commodity production in the natural environment, all these approaches fail to connect with political ecology, an important emerging area in critical theory (Peet and Watts, 1996). Significantly, these instances of neglect occur at the most politically sensitive sites along commodity chains, preventing the concept from uniting, in a comprehensive blend of politics, consumption, culture, labor, and nature.

Expanded Version of Commodity Chains

In a more complex model of commodity chains, the effects of the commodity at the consumption node, the social and natural conditions at the production node, and the complex intersections of commodity chains at various intermediating and terminal points, are added to a simple model of commodity movement. This expanded version integrates the generation of cultural (signifying and representational) effects at the consumption node with the social and natural conditions at the production end of the chain, the purpose being to show the effects of one on the other, bringing home to consumers the results of consumption. In contrast to earlier theories, this expanded formulation sees commodity movements (the vertical dimension) connecting nodes that are conceived as places (horizontal dimensions) located at different positions along commodity chains. This emphasis on place lends the analysis potential for bringing together several aspects of the production and consumption of commodities. In this vein, the commodity chain is posited as a way of tying together material and signified realities, consumption and production, and activities separated by space, providing a fuller interpretation of the material world and the real, human actors who live in it (Hartwick, 1998).

This version has underlain various works in which commodity chain analysis is tied with issues of development and global trade. The seminal work by Bardnt follows the tomato commodity chin from Mexican fields to Canadian supermarkets, exploring all the various nuances of the chain, temporally and spatially (Bardnt, 2002). Others have explored various commodity chains such as cocoa and cotton, moving from the local level to the points of where these goods are consumed miles away (Ryan, 2011; Moseley and Gray, 2008). A more recent aspect is to add speculation in commodity markets like the New York Mercantile Exchange as the controlling mechanism. Many commodities are traded as 'futures' divorced from real, material goods, and even further

removed from workers, environments, and even consumers who pay higher prices for the same commodity (Peet, 2011).

Consumption Nodes

At the terminal nodal point of consumption, the radiating image of a commodity produces a halo effect of socially constructed meanings. Such meaning systems can be analyzed in a number of ways, including the aesthetics of representation and consumer taste. The preferred theoretical tradition is the semiotics of Peirce (1931–1935). In such a materialist social semiotics, a commodity has two meanings: a first-order meaning at the level of function; and a second-order imputed meaning at the level of symbolic effect. Semiotic analysis tries to reveal the social prescription of the meaning of a commodity. In a postmodern sign economy, first-order meanings, based in physical needs, have been transformed into second-order representational meanings, emanating from social status and cultural allusion (Gottdiener, 1995). However, for a complete explanation, the conditions of production must be included within social semiotic analysis. Stark contrasts in material and cultural conditions so intensify second-order symbolic meanings that they mutate into a third, specifically geographical, meaning-form. Images are usually added to commodities at, or near, the organizational centers of global trading systems, where the producers of sign value share the cultural norms of the consumers. Underdevelopment, unequal exchange, profit flows and power differences, vastly different conditions of life, must be hidden behind the image of the commodity to give the impression that consumption is effortless and has no negative side effects. In general, adding social semiotics to commodity chain analysis expands the horizontal analysis of commodities at the consumption end and creates awareness of vertical linkages to producers (Hartwick, 1998).

Production Nodes

The conditions of production at the other terminus of the commodity chain include the social relations of production, relations with the state, relations between workers and families, hence the reproduction of the household. This, in turn, consists of social relations of reproduction (gender, class, ethnicity) and social relations with nature, including the worker-family's reproductive use of subsistence land and resources. The complete set of the conditions of existence of the producers, and the full range of natural conditions of production that enter into the materiality of the commodity, and pass thereby into the distant bodies of consumers, are explored. Of importance too is the relation between commodity production, inequality and development: many Third World states are trying to escape their roles as mere suppliers of raw materials and move into more advanced stages of the chain (Talbot, 2002; Heintz, 2003).

Commodity Bundles

Commodity chains articulate one with another at various nodal points of the intersection of their pathways. At the production end, commodities of prime significance form the conditions of existence for secondary commodity chains. At other significant nodes, processing points in particular, chains converge into commodity bundle that make up imaged complexes entering the consumption node – the entire complex combines to signify status, wealth, and power through radiating interconnected significations. As Glennie and Thrift (1992) note, any commodity chain is characterized by leakiness, in both material and symbolic ways, which influences other commodity chains – they catalog the intertwining between, advertising of linked products, consumer reflexivity, and consumption across several commodity systems. Nodes of consumption are thus points of convergence for series of imaged complexes of commodity chains. In this last sense, each purchase in the market is seen as culminating in an entire complex of commodity production and representation, linking together several lines of waged workers, unwaged reproducers of waged workers, and natural resources.

Commodity Chains and the Politics of Consumption

Geographical analysis centered on commodity chains connects the generation of cultural (signifying) effects within consumption to the real and material (social and natural) conditions involved in production. Deconstruction, understood in a geographical and materialist sense, uncovers these hidden dimensions of the commodity sign. Moving to a geographical focus on place broadens commodity analysis giving it greater political potential as a critical tool. Using this device, a series of local worlds are linked by connecting-chains into global systems. Commodity chains enable a greater awareness of the geographical implications of the political economy of consumption. Informed by commodity chain analysis, consumers learn to deconstruct, or critically analyze, the disconnected messages that bombard them by reconnecting images with material realities. However, companies also learn too in terms of adding a veneer of social responsibility to their normal business practices (Hughes, 2006). Also the focus on people-in-places, as key nodal points along a commodity chain, broadens economic analysis so that social, cultural, and natural relations can be incorporated. This gives commodity chain analysis greater political potential as a comprehensive political tool. Formulated in this way commodity chains are said to constitute an analytical basis for a transformative politics (Hartwick, 2000).

Common Law

Simon Roberts, London School of Economics and Political Science, London, UK

Abstract

This article on the common law examines its nature, utilization, historical development, geographical diffusion, theorization, and likely future development.

Introduction

The term common law first came into use in England during the thirteenth century. It referred to the 'common' repertoire of norms and understandings that had begun to be recognized across the whole realm during the latter half of the previous century, as central government was becoming consolidated. These widespread common understandings, which were seen to contrast with surviving customs of a simply localized character, became institutionalized as law as they were invoked to underpin the decisions of judges in the royal courts. In short, this evolving common law claimed to represent the immemorial understandings prevailing in the social world and was at the same time put to use as an instrument of rule by the courts as they developed into a distinctive branch of government. This primary sense of the term common law has survived and continues in use, particularly as a means of contrasting this source from others that the English courts now draw on concurrently – 'statute' and 'equity' (q.v.). But the term has now acquired a general secondary sense in identifying the broader legal domain formed through the diffusion of English law under the process of colonial expansion. This common law world is contrasted with that occupied by the codified civil law systems of continental Europe directly inspired by Roman law and those originating in them.

Historical Development in England

While the common law is seen to originate in the everyday practices and understandings of the social world, its growth from the twelfth century took place in the context of dual, linked processes: the progressive consolidation of central government and the gradual emergence of a specialist legal profession. This growth was realized through the discursive formulation of 'law' in the pleadings of lawyers and the judgments given in the Royal courts. It was associated from an early stage, and remains associated today, with one primary assumption and a distinctive method. The assumption was that the common law sought to realize and secure the practices and understandings of everyday life (immemorial custom). The strength of this assumption can be illustrated through numerous examples, such as the continuing invocation of the reasonable man in arriving at the appropriate standard of care in respect of claims arising from civil wrongs (tort); the care taken to ascertain normal business practice in the area concerned when judging commercial disputes; and the deference accorded to the customs of conveyancers by courts dealing with property disputes. The method distinctive to the common law lay in the procedure under which lawyers recovered the rules to underpin their arguments, and judges to justify their decisions, from the records of earlier judgments. This procedure, the doctrine of precedent, was made possible by the maintenance from an early stage of semiofficial written records (the *Year Books*) and subsequently sustained by private series of reports before official law reporting became institutionalized. Consistency in decision making was reinforced by the understanding that courts should wherever possible follow their own previous decisions and were obliged to follow those of courts superior to them in the judicial hierarchy (the doctrine of *stare decisis*). This procedure can be contrasted with the mode of decision associated with the continental civil law world under which the judge seeks the rules to ground a decision in an authoritative, ultimately codified, text.

The working practices that fashioned the common law were facilitated by the close relationship prevailing from medieval times between the judges and the specialist groups that ultimately became the legal profession. Notwithstanding the strong historical link between adjudication and the consolidation of government, in England there has never been a career judiciary. Even in recent times, the higher ranks of the judiciary have been recruited exclusively from the legal profession, with appointment to the 'bench' representing the ultimate career stage of the successful lawyer. While some elaborate ritual, including the conferment of knighthood in the case of the higher judiciary, marks the transition from barrister to judge, and some formal distance is subsequently maintained between judges and their former colleagues, judges remain sociologically very much part of the professional group from which they emerge. They continue to belong to long-established networks of information exchange and support – often crossing generations – begun in the great private schools, continued at university, and subsequently prevailing in the collegiate groups to which barristers belong (the Inns of Court). So the courts can be just as easily seen as the apex of the legal profession as a specialized branch of government.

The common law that developed in the King's courts through resort to precedent has traditionally been contrasted with two other sources of law. The first of these has been described by legal historians as arising directly out of the formal working practices of the King's courts. These were characterized from an early stage by procedures requiring anyone who sought redress to bring the claim within one of a limited number of elaborate written formulae (known as

writs). If some mistakes were made in the pleadings, the claimant would be denied his remedy. Ensuing direct appeals for help to the King, which such apparent injustices gave rise to, led to the growth of a parallel remedial jurisdiction presided over by the Lord Chancellor. This jurisdiction, known as equity, had a distinct body of doctrines, rules, and practices, and was long administered in separate courts.

Both the common law and equity evolved alongside, and are contrasted with, statute law – rules promulgated by the sovereign. While progressively larger areas have become at least partially regulated by statute – notably in the fields of crime, commercial law, and property – a comprehensive legislative scheme of the kind introduced through the great continental codes of the eighteenth and nineteenth centuries has never been attempted in England. This more limited role and reach of legislation provides a further contrast with the civil law regimes of continental Europe.

The 'rediscovery' of Roman law in Italy during the eleventh century is generally presented by historians as having a limited effect on the growth of the common law in England. But England was in no sense isolated from this learning. Some of the clerics who accompanied William I to England were distinguished as scholars of Roman law, so Justinian's great *Digest* was well known there from an early stage. Holdsworth also makes it clear that Bracton, a senior judge writing in the mid-thirteenth century, used Roman law to fill the gaps left by his extensive repertoire of case histories. But while Roman law provided part of the intellectual climate within which a unified legal order evolved in England during the medieval period, its use as a direct source was limited. Even during the English Renaissance, the legal historian Maitland notes that the common law was still characterized by "an amazingly continuous persistence of medieval doctrine." He attributed this durability to the presence of the collegiate groups, the Inns of Court, within which English lawyers associated. He saw the medieval Inns as 'schools of law' that provided arenas of communication within which young lawyers were taught and their seniors formulated a coherent repertoire of legal doctrine. He wrote: "What is distinctive of mediaeval England is not parliament, for we may everywhere see in Europe assemblies of estates … but the Inns of Court and the Year Books that were read therein, and we shall hardly find their like elsewhere." By the time of the great continental codifications of the eighteenth and nineteenth centuries, which were closely informed by Roman law, the evolving understandings and practices of English judges and lawyers were already part of a largely autonomous, differentiated legal order. By then, the common law tradition was too well set to be disturbed.

Geographical Diffusion of the Common Law

While originating in England, the common law has undergone wide diffusion as English settlers carried it with them abroad, and the government at Westminster imposed it upon annexed or protected territories in the course of colonial expansion. Across India, North America, Australasia, and considerable areas of Africa and Asia, the common law remains today a significant component, linking together a range of independent legal orders. Following the now ancient precedent of the United States of America, most former colonies have retained significant elements of the common law, justifying the shared label of the common law world. But the sheer diversity of contemporary arrangements within this loose association inevitably makes any generalization hazardous.

English settlers establishing colonies overseas took with them the general law of England as it stood at the moment of first settlement. By this means, the common law was established as the foundational law of the United States and those regions of what became the British Commonwealth that were subject to settlement. In these cases, very little recognition was initially given to the existing laws and customs of indigenous peoples. In those further territories that were conquered, annexed, or declared protectorates as the British colonial empire subsequently expanded, the statutes of general application, common law, and doctrines of equity in force in England at the time were typically imposed by Order in Council from Westminster. In these latter cases, notably in India and Africa, early recognition was given to diverse local legal orders encapsulated in the course of colonial expansion. In the case of Africa, this recognition extended to indigenous dispute institutions. Elsewhere, notably in Canada and Australasia, recognition of the prior arrangements of indigenous peoples was postponed well into the twentieth century (*see* Indigenous Rights).

Once English law, including its major common law component, had been received in a colony, it remained in force until repealed or modified by the local colonial legislature or courts – or by the overarching authority represented by the Parliament at Westminster and the Privy Council (the ultimate appellate tribunal of the Empire). These initial linkages between the metropolis and the colonial world have had variable duration. In the case of the American colonies, they were severed early on by the Declaration of Independence. During the twentieth century, they progressively disappeared in the self-governing Commonwealth countries, but some former colonial territories have chosen to retain a final appeal to the Privy Council.

Beyond the impetus given by the immediate necessity of explicit constitutional provision, the 'fresh starts' generated by the colonial enterprise resulted in vigorous, eclectic localized growth for the common law. In these new local contexts, the energy to attempt rationalization, even toward codification, was perhaps greater than in the metropolis. Major initiatives included the codification of wide areas of private law and the criminal law undertaken in India. The Indian Penal Code was subsequently reused in modified form in several other colonial territories. In the United States of America, with the particular problem of its numerous private law jurisdictions, a general attempt at rationalization has been the American Law Institute's Restatement of the Law. This initiative, now in its third generation of restatements, has brought together judges, lawyers, and professors in the preparation of an agreed statement of common law across the state jurisdictions. In the same context, the great American law schools have on the whole self-consciously attempted to present an overall view of the common law in their teaching and research (*see* Legal Education). Elsewhere across the postcolonial world, the superior courts in different jurisdictions have become increasingly attentive to each other's formulations, indicating explicitly in

their judgments that they are working together on a shared overarching fabric that is in the widest sense a common law.

Theorization of the Common Law

Attempts to 'theorize' the common law, in the sense of drawing together rules and procedure for the purposes of exposition and commentary, were made from a very early stage. Holdsworth even proposed that Glanvil's compilation, prepared sometime toward the end of the twelfth century, "marks the true beginning of the common law." Judge Bracton's great treatise, compiled on the basis of 2000 cases that he had collected from the plea rolls, followed in the mid-thirteenth century. Both Glanvil and Bracton were deeply involved in what was becoming specialized, legal administration and for the remainder of the medieval period the common law continued to reside in practice, receiving discursive formulation only in the judgments of the courts and in authoritative commentaries. All the great legal texts of the period were prepared by practitioners whose learning was acquired through their work and in the context of their specialist associations, the Inns of Court.

Just as native legal theory in the medieval period concentrated on parochial commentary, that of the early modern period continued to focus largely on the immediate practicalities at hand. During the constitutional crisis early in the seventeenth century, Chief Justice Coke eloquently prioritized the relative authority of judges, King (he "hath no prerogative but that which the common law allows him"), and Parliament. But Coke's arguments were not distanced speculation; they rather reflected the workings of a practical mind, the holder of high office seeking to justify his position in the urgent context of struggles for power.

Prior to the mid-eighteenth century, the common law had never been the subject of exposition and research in English universities. English university teaching of the common law can be said to begin with the lectures that William Blackstone, the first Vinerian Professor, delivered at Oxford in 1758. These lectures were subsequently published in his famous *Commentaries* (1765–69). The *Commentaries* took more the form of popular exposition than scholarly treatise; but the account he gave provided a framework that would remain readily recognizable even 200 years later. In this work, the common law takes pride of place as the law by which "proceedings and determinations in the king's ordinary courts of justice are guided and directed". The validity of common law doctrines, "depending on immemorial usage for their support", is determined by the judges. In reaching judgment "it is an established rule to abide by former precedents where the same points come again in litigation."

It was only in the early nineteenth century that a body of specifically legal theory, focused on the common law tradition yet distanced from practice, began to develop in England. This body of theory links law firmly to government and maintains a consistent focus on adjudication. The link between government and law is established at the outset in the work of John Austin, the first Professor of Jurisprudence at University College, London. In *The Province of Jurisprudence Determined* (1832), Austin presents law as the command of a sovereign directed toward members of a society in a 'habit of obedience,' with failure to comply being met with 'sanctions.' That central association safely in place, English jurisprudence turned to focus – virtually exclusively over the next 175 years – on providing theoretical foundations for adjudication.

The first modern attempt to provide a general theory of adjudication was made by Henry Maine in *Ancient Law* (1861). In this work, taking a broad comparative, historical sweep, he insisted on locating the core of law in adjudication and in the emergence of rules underpinning judicial decision making. He began by mapping out a broad transition from small kin-based groups to larger, territorial units. The very origin of social life was identified in the steering role exercised within a group of kin by the senior male agnate. These old patriarchs made decisions on an ad hoc basis; no consistent rules underpinned the decisions they took, yet government was supposed to be by adjudication by the senior male, before whom all disputes were brought. In the form of society that followed, numbers of these small groups of agnates became clustered together under chiefs, but the (sometimes fictional) assumption of shared kinship remained the basic organizing principle. Then came the territorial stage, in which members identified themselves through their common occupation of a defined tract of land, rather than through kinship. Around the end of the second stage and the beginning of the third, 'law' developed as rulers began to pronounce the same judgments in similar situations, providing their decision making with an underlying set of rules. Later in the development of territorially based societies, the settlement of disputes fell into the hands of a specialized elite, who alone had access to the principles to be followed in their resolution. As Maine wrote: "What the juristical oligarchy now claims is to monopolize the knowledge of the laws, to have the exclusive possession of the principles by which quarrels are decided." There followed the 'era of codes,' and so on; but we can leave the developmental process at this stage.

Several important features are clear from this summary. First, there is the focus on dispute resolution and the foregrounding of a particular mode of intervention. For Maine, there were no structural changes in the dispute settlement process over the fundamental stages of societal development. From the senior male agnate onward, disputes were resolved by decision, handed down by a third party; there was no suggestion of negotiatory modes of settlement giving way to processes of third-party adjudication. Second, the presence of a normative basis for decision making was the key attribute of law for Maine, and the emergence of this feature heralded the transition from the prelegal to the legal world. Third, there was the later development of specialization as legal rules became separated off from other rules operating in society. So for Maine, social life is the product of 'government,' and the key variables lie in the identity of the third parties responsible for adjudication and in the evolving criteria underpinning decisions.

After Maine, the perfection of theories of law as adjudication occupied the jurisprudence of the common law world through the rest of the nineteenth century and much of the twentieth century. Much of this scholarship was generated in North America where thorough-going reexamination was made of the doctrines of precedent and *stare decisis*. The greater part of this work remained within the traditional commentary mode

of legal scholarship, exemplified by Goodhart's now classical attempts to refine the doctrine of precedent. More ambitiously, scholars like Frank and Llewellyn of the legal realist school drew on sociological perspectives in questioning vigorously whether these doctrines actually operated in the manner claimed in native legal theory. They indicated the relative freedom of judges to distinguish previous decisions they did not want to follow, suggesting that rules were drawn from the repertoire to justify desired outcomes as opposed to determining what those outcomes would be. This iconoclastic strand survived on to the end of the twentieth century in the work of the critical legal studies movement.

One notable attempt to escape from the grip of adjudication, and to think about law unconstrained by the institutional shapes of the modern state, was made by Hart (1961). Rejecting Austin's command theory as simplistic and in some respects inaccurate, Hart's elucidation of law lays central emphasis on rules. One essential category of these is made up of 'primary rules' imposing obligations. The distinguishing mark of such a rule is the seriousness of the pressure to conform to it: "Rules are conceived and spoken of as imposing obligations when the general demand for conformity is insistent and the social pressure brought to bear upon those who deviate or threaten to deviate is great."

While Hart concedes that a society might exist with primary rules only, they alone do not constitute a legal system. For the step from 'the prelegal into the legal world' to be made, these primary rules must be supplemented with 'secondary rules' of three kinds: rules of recognition making it possible to identify what the primary rules are; rules of change providing for the alteration of primary rules when the need arises; and rules of adjudication empowering certain people to determine whether on a given occasion the primary rules have been broken. Most systems will also contain other secondary rules authorizing the application of penalties where primary rules are violated, but this further refinement is not seen as essential to a legal system.

Through the device of these secondary rules, Hart appears to disassociate his model from any parochial institutional content and invest it with considerable value for cross-cultural purposes. However, the escape seems to be illusory, leaving Hart's account of law firmly grounded in the institutions of the state and state-sponsored adjudication. He himself recognizes that the three categories of secondary rules imply, and require, the presence of legislative and adjudicatory agencies. While Hart struggled to marginalize adjudication by identifying law as an affair of rules, subsequent exegeses of his work hastened to re-present his core idea as a theory of adjudication. It is significant too that his most influential successor, Ronald Dworkin, has consistently refocused the task of jurisprudence on understanding and justifying judicial decision making.

The Direction of the Common Law

Close links with government and a core role in providing trial and judgment have historically been central to the understandings of what a 'court' is in the West. Under the ideology of the rule of law, 'justice' has been conceptualized in terms of command realized through reasoned judgment, and judges have been thought of virtually exclusively in those terms. This dominant neoclassical image of the court persists in the cosmologies of the common law world, an apparently essential and enduring component of the ideology of legalism. Yet it does so in the face of widely recognized transformations. Over the last 30 years, it has become generally acknowledged that lawyers routinely use the procedural path of litigation for their settlement negotiations and that the number of civil trials has gradually decreased. Latterly also, the articulated priorities of government, and of the courts themselves, have shifted dramatically. Sponsorship of settlement is now explicitly identified as the courts' primary responsibility, with supervision of trial and the delivery of judgment becoming residual, the solution of last resort. So common law courts are today sites where the profoundly different rationalities that ground rule-based adjudication and negotiated agreement coexist and interact.

In England, for example, this 'culture of settlement' has been advocated by the higher judiciary, adopted as government policy, enshrined in a new regime of civil procedure, and increasingly realized in court practice. In broad, schematic terms, the procedural regime introduced through the Civil Procedure Rules of 1998 promoted settlement through two radical changes. First, through Pre-Action Protocols, a wholly new prelitigation field is marked out under which information exchange and negotiation is required prior even to the filing of a claim if the possibility of later cost sanctions is to be avoided. So the procedural framework is now designed to enforce and police negotiations in the prelitigation phase, with governmental intervention reaching out into what was previously the private sphere. Second, once a claim is filed, the dispute moves into a phase of 'case management' during which the parties are subject to judicial supervision as they move along the procedural route at the end of which lies the theoretical possibility of trial and judgment. So even once 'litigation' is formally commenced, settlement continues to be prioritized.

In the face of these profound transformations, a clearer, empirically based understanding of what happens in today's common law civil courts is required. This needs, as Martin Shapiro argued in his seminal book *Courts* (2005), to be supplemented with 'a more general theory of the nature of judicial institutions.' But the argument here demands going beyond Shapiro's call to expand the neoclassical model to allow for a mediatory element. The folk model of the court as agent of trial and judgment no longer provides a plausible analytic starting point. Instead, recognizing that civil courts no longer correspond to the neoclassical model, and that they today reconceptualize their primary role as the sponsorship of settlement, there is a need to begin again by examining empirically both how they are in practice used by their lay clientele and the professionals representing them, and how court personnel have both actively sponsored and responded to that changed use.

How then should the court be reconceptualized in the light of the new ideological priority attached to 'settlement' in the legislative and judicial cosmologies? Clearly, an idealized conceptualization of the court as agent of trial and judgment can no longer be maintained when this is no longer the way in which the judges represent themselves or an accurate reflection of the operational reality on the ground. The conclusion must be that it is time to reconceptualize the court as an arena for

structured bilateral negotiations, one in which the dominant mode of interaction is an often protracted conversation between the parties themselves. This is a drama in which both active judicial sponsorship of settlement and the theoretical availability of trial and judgment provide a background structure to the process. But beyond that they play a residual role.

Well before the procedural reforms introduced at the end of the twentieth century, it was widely acknowledged that most civil cases settle. But with the officially sanctioned move of courts to provide arenas for bilateral negotiation, the dislocation between form and substance increases. The courts – buildings with now often empty courtrooms – take on an increasingly symbolic character, just as the judges now appear as 'exemplary,' ceremonial figures, legitimating other peoples' decision making. Arguably, with this decline in the importance of command, the decay of an operational/practical role, the ceremonial, ritual dimension increases in importance. Symbolism and ritual are what the court provides. No longer required to mask and justify the power exercised through the court's own commands, these dimensions now legitimize the decision making of the parties themselves.

Common Rule: US Regulatory Protections for Human Research Participants

Carl H Coleman, Seton Hall University School of Law, Newark, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Common Rule, more formally known as the Federal Policy for the Protection of Human Subjects, applies to human subjects research conducted or supported by 15 US federal agencies, as well as to privately funded research conducted at most institutions that receive federal research funding. Covered research must be reviewed and approved by an institutional review board, which must determine that the risks of the study have been minimized; the risks are reasonable in relation to the anticipated benefits; adequate plans exist for obtaining participants' informed consent; and other ethical issues have been appropriately addressed.

The US regulatory protections for human research participants emerged in the early 1970s, following a series of public revelations about unethical medical experiments. In a 1966 article in the *New England Journal of Medicine*, the physician Henry Beecher documented 22 'unethical or questionably ethical studies' in the United States, including experiments in which mentally retarded children were deliberately infected with the hepatitis virus and a study in which live cancer cells were injected into indigent, chronically ill, elderly patients (Beecher, 1966). A few years later, the *New York Times* reported a study that the US Public Health Service had been conducting in Tuskegee, Alabama, over a period of four decades, in which treatment was deliberately withheld from poor, African-American men with syphilis so that scientists could study the 'natural course' of the disease (Jones, 1993).

In response to these and other incidents, Congress enacted the National Research Act in 1974. The Act requires any entity that receives federal funds to conduct biomedical or behavioral research involving human subjects to establish oversight committees known as 'institutional review boards,' or IRBs. The Act also established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research and charged it with identifying basic ethical principles for research and recommending guidelines for research supported with federal funds. The result of the Commission's work was the 1979 Belmont Report: Ethical Principles and Guidelines for the Protection of Human Subjects of Research. The report identified three basic ethical principles relevant to all research with human participants: respect for persons, or the protection of individual autonomy; beneficence, or the maximization of benefits and minimization of risk; and justice, or the equitable distribution of the benefits and burdens of research (National Commission, 1979).

In 1981, the Department of Health and Human Services (DHHS) revised its regulations governing research with human subjects, using the ethical principles articulated in the Belmont Report as the overarching framework. Ten years later, DHHS, along with 14 other federal agencies that conduct, support, or otherwise regulate human subject research, promulgated a new set of regulations called the Federal Policy for the Protection of Human Subjects, or, more simply, the Common Rule. Each of these 15 agencies has published an identical version of the Common Rule in its own section of the Code of Federal Regulations (CFR). References to the Common Rule usually refer to the version published by DHHS, which is located at 45 CFR part 46.

The Common Rule includes only Subpart A of 45 CFR part 46, which contains the general requirements applicable to all research involving human participants. Part 46 contains three additional subparts dealing with special categories of research: Subpart B covers research with pregnant women, fetuses, and neonates; Subpart C covers research with prisoners; and Subpart D covers research with children. There is also a Subpart E, which sets forth requirements for IRB registration. These additional Subparts are not part of the Common Rule, and only some of the other Common Rule agencies have adopted them.

The Common Rule applies to any research that is conducted or supported by one of the agencies that has adopted it. For example, if the National Institutes of Health (NIH), which is part of DHHS, awards a grant or contract to a university to conduct a human research study, that study would be subject to the Common Rule requirements. In addition, any institution that receives federal research funding must enter into an 'assurance' with the government that explains the standards the institution will apply to nonfederally supported research, such as studies sponsored by industry or private foundations. At a minimum, the institution must agree that nonfederally supported research will comply with the general ethical principles articulated in the Belmont Report. Most institutions, however, go further and agree that all of their research will adhere to the full Common Rule requirements, even studies that are not supported by federal funds (Coleman et al., 2005).

The applicability of the Common Rule does not depend on where the research will be conducted; even studies conducted entirely outside the United States may fall within the Common Rule's reach. However, the Common Rule recognizes that "[w]hen research covered by this policy takes place in foreign countries, procedures normally followed in the foreign countries to protect human subjects may differ from those set forth in this policy." To accommodate these differences, it authorizes agencies to permit institutions to rely on foreign procedures if those procedures 'afford protections that are at least equivalent' to those contained in the Common Rule. Yet, because DHHS has never deemed any other country's human research protections to be 'equivalent' to those in the Common Rule, the option of substituting foreign procedures remains more theoretical than real (Dove et al., 2014).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.11024-4

Research covered by the Common Rule may also be subject to additional human participant protection requirements. For example, any study involving products regulated by the Food and Drug Administration (FDA) – i.e., drugs, medical devices, or biologics – must also comply with the FDA's human subject protection rules, regardless of the study's funding source. Health care organizations and their 'business associates' are also required to comply with privacy and security regulations enacted pursuant to the Health Insurance Portability and Accountability Act. Institutions that receive NIH funding are subject to additional rules regarding the disclosure and management of research-related conflicts of interest. In addition, the Common Rule does not displace state laws that provide additional protections to research participants, nor does it preclude research institutions from adopting stricter rules as a matter of their own institutional policies.

Activities Covered by the Common Rule

The Common Rule applies only to activities that meet the definition of 'research' with 'human subjects.' Research is defined as "a systematic investigation … designed to develop or contribute to generalizable knowledge." This definition is intended to exclude situations in which the information being collected will only be relevant to the particular individuals who are involved in the project, such as a single individual or small group of people in a particular setting (Coleman et al., 2005).

It is not always easy to determine when an activity is 'designed to develop or contribute to generalizable knowledge.' Consider, for example, a hospital that collects data from the medical charts of surgery patients to better understand hospital-specific circumstances leading to infection, such as the choice of nursing staff or the scheduling of procedures. On the one hand, because the data collected from this intervention will be specific to the particular hospital, one might conclude that the results are not capable of being generalized to other settings, where the staffing and scheduling issues are likely to be different. On the other hand, staffing and scheduling issues that cause problems at one hospital might also cause problems at other hospitals with a similar patient and staff makeup, potentially making it possible to generalize the results of the intervention to other settings (World Health Organization, 2013).

In situations like this, it has been suggested that the applicability of the Common Rule depends on the intent, or purpose, of those who designed the activity. As explained by the US Centers for Disease Control and Prevention (CDC), "If the purpose is to develop or contribute to generalizable knowledge, the project is research." The CDC has defined term 'generalizable knowledge' as "new knowledge that has relevance beyond the population or program from which it was collected, or information that is added to the scientific literature" (Centers for Disease Control and Prevention, 2010). Thus, if the purpose of those who designed the activity were simply to provide information for an internal process of quality improvement, the activity would not constitute research and would not be subject to the Common Rule.

Even if a particular project meets the definition of 'research,' it will not be subject to the Common Rule unless it also implicates the regulatory definition of 'human subject.' The Common Rule defines a human subject as "a living individual about whom an investigator … obtains (1) data through intervention or interaction with the individual; or (2) identifiable private information." Thus, studies involving the review of documents containing individually identifiable personal information would implicate 'human subjects' under the definition, even if the investigators never interact with the individuals. Similarly, studies in which investigators speak or otherwise interact with individuals would also involve human subjects, even if no individually identifiable information were ever obtained.

The Common Rule identifies some activities that – despite meeting the definition of 'research' with 'human subjects' – are, nonetheless, exempt from the Rule's usual requirements. The exemption that is most relevant to the social and behavioral sciences applies to research involving the use of educational tests, survey procedures, interview procedures, or observations of public behavior. Such studies are exempt from the Common Rule unless (1) the researcher will be recording identifiable information about the participants; and (2) disclosure of the information could place the participants "at risk of criminal or civil liability or be damaging to the subjects' financial standing, employability, or reputation." In light of this exemption, survey or interview studies in which no identifiable information about the participants will be recorded are exempt from the Common Rule, even if the questions being asked are sensitive and may cause the participants psychological distress.

Although research that falls into one of the exemption categories is not subject to the Common Rule, most institutions require investigators who engage in such research to submit their studies to the IRB, so that the IRB can confirm that the requirements for the exemption have actually been satisfied. Some institutions go further and subject exempt research to at least a minimal form of ethical review. By contrast, activities that do not meet the regulatory definition of 'research' or 'human subject' can be undertaken without any involvement of the IRB at all.

Institutional Review Boards

The Common Rule gives IRBs the primary responsibility for ensuring that studies subject to its jurisdiction conform to the Common Rule and the ethical principles articulated in the Belmont Report. Studies subject to IRB review may not be commenced until the IRB has affirmatively granted approval. In addition, IRBs must provide 'continuing review' of ongoing studies at least once per year.

IRBs must have at least five members with a diversity of experience and expertise. IRBs may not consist "entirely of members of one profession," and "every nondiscriminatory effort" must be made to ensure that IRBs include both men and women. In addition, each IRB must include "at least one member whose primary concerns are in scientific areas and at least one member whose primary concerns are in nonscientific areas," as well as "at least one member who is not otherwise affiliated with the institution and who is not part of the immediate family of a person who is affiliated with the institution." Certain categories of studies deemed to involve no more than minimal risks to participants may be reviewed by expedited procedures, in which a single IRB member has the

authority to grant approval without the involvement of the full board. A list of studies eligible for expedited review is available on the DHHS web site.

The 'I' in IRB refers to the fact that most of these committees operate as part of the institutions conducting the research. The National Commission considered this sort of 'local' review as an essential part of the system of human subject protection. The Commission reasoned that "local committees have the advantage of greater familiarity with the actual conditions surrounding the conduct of research" and can ensure that the process of ethical review incorporates local attitudes and values (Peckman, 2001).

In recent years, however, two important developments have challenged the locally based IRB system. The first is the emergence of independent IRBs that are not part of any research institution – in essence, 'noninstitutional review boards.' These boards are hired by research sponsors, including commercial entities such as pharmaceutical and medical device companies, and often operate on a for-profit basis. Some commentators believe that the fact that these IRBs are paid by research sponsors creates an inappropriate conflict of interest. However, others suggest that these conflicts of interest are less problematic than those that arise in traditional institutional-based IRBs, where reviews are conducted by researchers' professional colleagues (Heath, 2001).

The second development challenging the locally based nature of IRB oversight is the increasing use of multisite studies. While it is still common for multisite studies to undergo IRB review at each institution where the study will be conducted, this practice has been criticized as both ineffective and inefficient (Menikoff, 2010). Various mechanisms have been developed to reduce the use of duplicative IRB reviews, including procedures allowing institutions to delegate their review responsibilities to other institutions and the use of centralized or multi-institutional IRBs (Wagner et al., 2010).

Criteria for Approval of Research

Before an IRB approves a study, it must determine that the risks to participants are minimized; the risks are reasonable in relation to anticipated benefits; the selection of participants is equitable; the process for obtaining and documenting informed consent is appropriate; and, when appropriate, there are adequate provisions for data and safety monitoring and ensuring privacy and confidentiality. The regulations also provide that 'additional safeguards' must be provided if participants "are likely to be vulnerable to coercion or undue influence, such as children, prisoners, pregnant women, mentally disabled persons, or economically or educationally disadvantaged persons." The Common Rule does specify what these additional safeguards might entail, although, as noted above, DHHS and a few other federal agencies have adopted additional regulations applicable to research with pregnant women, prisoners, and children.

Risk-Benefit Assessment

Assessing the risks and potential benefits of research is one of the IRB's core responsibilities. First, the IRB must determine that the risks have been 'minimized' by using procedures that are 'consistent with sound research design' and 'do not unnecessarily expose subjects to risk.' The regulations provide that, 'whenever appropriate,' researchers should use procedures that are "already being performed on the subjects for diagnostic or treatment purposes."

Second, in addition to ensuring that the risks have been minimized, the IRB must determine that the risks are "reasonable in relation to anticipated benefits, if any, to subjects, and the importance of the knowledge that may reasonably be expected to result." This balancing process is inherently uneven. On the risk side, the IRB's focus is limited to the risks to the subjects in the study. The regulations specifically provide that IRBs "should not consider possible long-range effects of applying knowledge gained in the research (for example, the possible effects of the research on public policy) as among those research risks that fall within the purview of its responsibility." On the benefits side, however, the IRB considers not only potential benefits to subjects, but also the "importance of the knowledge that may reasonably be expected to result." In light of this language, it is clear that the IRB may approve research even if there are no anticipated benefits to the subjects in the study, provided the knowledge expected to be gained from the research is sufficiently important.

In assessing the risks of research, IRBs are expected to consider not only the potential for physical harm, but also the possibility of psychological, social, economic, and other types of injuries (Prentice and Gordon, 2001). For example, in some studies, the unauthorized release of sensitive personal information could cause embarrassment or possibly discrimination and harassment. The existence of these risks does not mean that the study cannot be conducted, but the IRB needs to assure itself that the risks have been minimized as much as reasonably possible, and the anticipated benefits of the study are sufficient to justify the potential harms.

According to most commentators, when IRBs consider potential benefits to subjects, their focus should be on the direct benefits resulting from the research intervention itself – that is, the possibility that the intervention will produce its intended beneficial outcomes. In some cases, subjects may be offered various incentives to participate, such as free meals, small gifts, or even payments. However, these benefits are generally not considered to be the kind of direct benefits that IRBs should use to offset research-related risks (King, 2000).

Informed Consent

General Requirements for Informed Consent

With a few exceptions described below, researchers subject to the Common Rule must obtain written informed consent from the subject or, if the subject is unable to provide consent directly, the subject's 'legally authorized representative.' The term 'legally authorized representative' is defined as "an individual or judicial or other body authorized under applicable law to consent on behalf of a prospective subject to the subject's participation in the procedure(s) involved in the research." Because state law usually governs the process of providing consent on behalf of individuals who lack decision-making capacity, the effect of this provision is to delegate the definition of 'legally authorized representative' to the law of the

state where the research is taking place (or, if the research is taking place abroad, the law of the relevant foreign jurisdiction).

The Common Rule provides that informed consent must be obtained "only under circumstances that provide the prospective subject or the representative sufficient opportunity to consider whether or not to participate and that minimize the possibility of coercion or undue influence." It also requires that information provided during the consent process must be "in language understandable to the subject or the representative." This requirement implies not only that English-language consent materials must be translated for non-English speakers, but also that the level of the language used (whether English or otherwise) is likely to be understandable by the target population.

The Common Rule prohibits the use of "exculpatory language through which the subject or the representative is made to waive or appear to waive any of the subject's legal rights, or releases or appears to release the investigator, the sponsor, the institution, or its agents from liability for negligence." While this provision protects subjects' right to seek compensation for negligently caused injuries, it does not require compensation for harms caused in research that are not due to negligence. In this respect, the Common Rule differs from most international guidelines on research ethics, which require compensation for all research-related injuries, whether or not they are attributable to negligence (Presidential Commission, 2011).

Office for Human Research Protections (OHRP) has emphasized that informed consent is a 'process' that begins with "the initial approach of an investigator to potential subjects." This means that any advertisements or solicitations for subjects must be submitted to the IRB for review. IRB review is not required, however, for listings on web sites that are limited to the title and purpose of a study, a summary of the protocol, basic eligibility criteria, study site locations, and contact information (Table 1).

Unless otherwise waived by the IRB, subjects or representatives must document their informed consent in writing. Researchers may either ask the subject or representative to sign a written document that embodies all the required information, or instead to sign a 'short-form written consent document' stating that the required elements have been provided orally. If the short-form option is used, a witness must be present during the oral presentation. In addition, the IRB must approve a written summary of what is to be said during the oral presentation, and this summary must be given to the subject or representative and signed by both the person obtaining consent and the witness.

Waivers of the General Requirements for Informed Consent

The Common Rule authorizes IRBs to waive or alter the usual informed requirement in two sets of circumstances. First, the regulations allow the waiver or alteration of consent in studies related to public benefit or service programs, if the studies are to be conducted by or subject to the approval of state or local governments, and the research "could not practicably be carried out without the waiver or alteration." OHRP has suggested that this waiver would be appropriate in "a study of identifiable private information about program benefit recipients using 20-year-old records … if current contact information for those recipients is not available."

The second, are far more frequently used, waiver provision applies to certain types of 'minimal risk' research. The term 'minimal risk' is defined in the regulations to mean "that the probability and magnitude of harm or discomfort anticipated in the research are not greater in and of themselves than those ordinarily encountered in daily life or during the performance

Table 1 Elements of informed consent under the common rule

Unless the IRB has authorized a waiver or modification of the usual consent requirements, the following information must be provided to each prospective research participant:

1. A statement that the study involves research, an explanation of the purposes of the research and the expected duration of the subject's participation, a description of the procedures to be followed, and identification of any procedures that are experimental;
2. A description of any reasonably foreseeable risks or discomforts to the subject;
3. A description of any benefits to the subject or to others, which may reasonably be expected from the research;
4. A disclosure of appropriate alternative procedures or courses of treatment, if any, that might be advantageous to the subject;
5. A statement describing the extent, if any, to which confidentiality of records identifying the subject will be maintained;
6. For research involving more than minimal risk, an explanation as to whether any compensation and medical treatments are available if injury occurs and, if so, what they consist of, or where further information may be obtained;
7. An explanation of whom to contact for answers to pertinent questions about the research and research subjects' rights, and whom to contact in the event of a research-related injury to the subject; and
8. A statement that participation is voluntary, refusal to participate will involve no penalty or loss of benefits to which the subject is otherwise entitled, and the subject may discontinue participation at any time without penalty or loss of benefits to which the subject is otherwise entitled.

When appropriate, one or more of the following elements of information shall also be provided:

1. A statement that the particular treatment or procedure may involve risks to the subject (or to the embryo or fetus, if the subject is or may become pregnant), which are currently unforeseeable;
2. Anticipated circumstances under which the subject's participation may be terminated by the investigator without regard to the subject's consent;
3. Any additional costs to the subject that may result from participation in the research;
4. The consequences of a subject's decision to withdraw from the research and procedures for orderly termination of participation by the subject;
5. A statement that significant new findings developed during the course of the research, which may relate to the subject's willingness to continue participation will be provided to the subject; and
6. The approximate number of subjects involved in the study.

Source: 45 C.F.R. Sections 46.116(a) and (b).

of routine physical or psychological examinations or tests." If the IRB concludes that the research involves no more than minimal risk, then it is authorized to waive or alter the usual consent requirements provided it further determines that doing so "will not adversely affect the rights and welfare of the subjects" and the research "could not practicably be carried out without the waiver or alteration." In addition, it must consider whether it would be appropriate to provide subjects with 'additional pertinent information' about their participation after the intervention is over.

One of the most common areas in which IRBs are asked to waive informed consent is psychological research. Psychologists often seek permission to withhold information from subjects because, if the subjects knew what was going to happen to them and why, that knowledge could alter the very behavior that is being studied. A famous example of this so-called 'deception' research was Stanley Milgram's experiments in the 1960s designed to examine obedience to authority, which is discussed elsewhere in this volume. Deception research requires researchers to withhold one of the basic elements of informed consent – an explanation of the purposes of the research. As such, an IRB may not approve the use of deception unless it determines that the study involves no more than minimal risk; withholding information about the purpose of the study will not adversely affect the subjects' rights and welfare; the study could not practicably be carried out without deception, and that subjects will be debriefed about their experience after the intervention is over.

In addition to the provisions for waiving or altering the usual informed consent requirement, the Common Rule also allows IRBs to waive the usual requirement of obtaining a signed consent form. Such waivers are allowed if either the only record linking the subject and the research would be the consent document and the principal risk would be potential harm resulting from a breach of confidentiality; or the research presents no more than minimal risk of harm to subjects and involves no procedures for which written consent is normally required outside of the research context. An example would be a study in which a single blood sample will be taken from HIV-positive individuals, which will then be examined in a laboratory for purposes unrelated to the subjects' health care. In this case, the risk from the potential disclosure of the subjects' HIV status would likely be greater than the risk from the blood draw, which is minimal. Therefore, to protect the subjects' confidentiality, the IRB could decide to waive the requirement for obtaining a signed consent form, thereby enabling the study to proceed without any individually identifiable information ever being recorded.

Other Approval Criteria

The IRB's obligation to ensure the equitable selection of subjects stems from the ethical principle of justice, which requires a fair distribution of the benefits and burdens of research. The Common Rule directs IRBs to "take into account the purposes of the research and the setting in which the research will be conducted" and to consider "the special problems of research involving vulnerable populations, such as children, prisoners, pregnant women, mentally disabled persons, or economically or educationally disadvantaged persons." OHRP guidance emphasizes the importance of protecting vulnerable populations without depriving them of the benefits of research or the opportunity to participate.

The Common Rule also requires IRBs to ensure that studies provide adequate provisions for data monitoring in order to ensure the safety of subjects. The level of monitoring required will depend on the risks involved in the study. While formal data and safety monitoring plans are most often used in studies involving medical interventions, they also may be appropriate in social and behavioral research in which adverse events are foreseeable. Adverse events in social and behavioral research could include breaches of confidentiality, emotional distress, or impact on subjects' social relationships.

Finally, the IRB is required to ensure that adequate protections exist to protect the subjects' privacy and confidentiality. Commonly used protections include storing sensitive information in locked cabinets or password-protected computer files and limiting the number of people who have access to the information. In some situations, the best way to protect subjects' privacy may be to encourage the researchers not to collect identifiable information in the first place. As discussed above, if the only involvement of human subjects consists of educational tests, surveys, interviews, or observations of public behavior, and the researchers do not record any identifying information, the study would qualify for an exemption to the Common Rule.

Enforcement of the Common Rule

OHRP is the federal agency responsible for enforcing the Common Rule. As part of carrying out this mission, it enters into agreements, or 'assurances,' with institutions that conduct federally funded research. These assurances require institutions to affirm that their researchers will comply with all of the Common Rule requirements. Institutions are required to enter into assurances with OHRP if their employees or agents are 'engaged' in nonexempt human subject research. Engagement in research is defined as intervening or interacting with living individuals for research purposes or obtaining individually identifiable private information for research purposes.

OHRP also enforces the Common Rule through by conducting site visits, either randomly or in response to complaints. If OHRP determines that the Common Rule is not being followed, it may require the institution to engage in corrective action, including rereviews of protocols, implementation of new database management strategies, and education and training of investigators or IRB members. OHRP may also restrict, attach conditions to, or suspend an institution's assurance, or recommend the suspension or removal of an investigator or institution from a particular project. The most extreme sanction OHRP can recommend is debarment of an individual or institution. Debarment is a government-wide sanction that precludes the debarred person or entity from contracting with the federal government for any purpose.

The Common Rule does not provide a 'private right of action,' meaning that it does not give individuals the right to sue for violations of its provisions. However, some courts have held that the Common Rule's informed consent provisions create a standard of care "against which informed consent in

human subjects research will be compared where the case involved inadequate informed consent" (Mastroianni, 2006). As a result, violation of the Common Rule's informed consent provisions may be relevant if a research participant is injured and brings a state-law claim based on a theory of lack of informed consent.

Common Sense, Anthropology of

Michael Herzfeld, Harvard University, Cambridge, MA, USA

Abstract

Common sense is not uniform across all sociocultural groups. Anthropologists typically confront the differences among 'common senses' at the very start of ethnographic fieldwork; their informants treat as self-evident actions and other phenomena that to the anthropologists are opaque and sometimes even absurd. From anthropology's relativist and empirical perspective, claims to a universal rationality are themselves a parochial form of common sense. Western-inspired theoretical models such as rational choice theory thus actually resemble everyday habits of reasoning and rest on culturally parochial and historically shallow assumptions of universal validity. Still earlier claims to a higher form of reason, used to defend atheism and agnosticism against religious authority, are similarly revealed as local versions of common sense, and thus as culturally as well as historically contingent. By removing common sense from the realm of the banal, and treating it instead as worthy of critical dissection even as it appears in their own ordinary assumptions, anthropologists also bring their reflexive and critical understanding to bear on the relationship between common sense and power.

Frederic Harrison, in *The Philosophy of Common Sense* (1907: 9), seeks to understand the universal qualities of common sense as a reconciliation of science and religion. In so doing, he appears to take a position entirely consonant with modern relativism: "It is usual entirely to put aside the testimony of all the uncivilised or semi-civilised races. And thus countless myriads of intelligent human beings, as completely as our ancestors, as entirely links in the chain of progress as our own parents, are abstracted from the inquiry into the innate qualities of the human mind." On closer inspection, however, his argument rests on evolutionary assumptions that were central to Victorian epistemology and that constitute a core area of what is held to be common sense in much of the Western world today. This illustrates a problem that is at the heart of the present discussion: how to achieve a position of relative independence from the object of inquiry when that object is assumed to inform the analysis itself? Much as a critic of structuralism might suspect that its claims about human cognition make its analyses circular, so any investigation of common sense inevitably starts from common sense assumptions.

The solution, I suggest, lies in the comparative approach that remains the core of most theory in social anthropology. If we do not assume that common sense is universal but instead tackle the forms it takes in different cultural settings, we may achieve some purchase on this slippery topic. As Mary Douglas (1972: 28) succinctly expressed the matter, "We have to see that the categories and actual principles which we find in our own world present the same problems of rational justification that baffle us in the exotic worlds of foreigners." This is true – perhaps especially so – when we examine our own theory making. As the archaeologist Robert Dunnell (1982: 12), remarks, "In one way, common sense is culture – it determines the kinds of observations, the rules for assembling those observations into sense, and even what constitutes sense. As a sense-making system, common sense is functionally equivalent to theory in the sciences." The risk, as he points out, is that, once we recognize that all common sense is in fact culturally specific, we must also see that its role in theory building is inevitably ethnocentric. Perhaps this is why scholars have so often, as Jovchelovitch (2008: 432–436) has argued, often background the relationship between science and common sense as much as possible. For social and cultural anthropologists, there would be two main ways of addressing this weakness, in addition to keeping it in plain sight at all times: sustained awareness of the scholar's own role in the construction of the data and the arguments, marked, as I have already noted, by the principled use of the first-person pronoun; and a commitment to maintaining and increasing the comparative study of common sense claims in a context that also permits the critical inclusion of our own.

The latter requirement requires that we focus on the extraordinary variety of logics that constitute common sense for their exponents, and, very often, for them alone. We do not have to agree with Harrison's (1907: xiii) rather truculent observation that "the mass of what is called Metaphysics is the fruitless search after insoluble puzzles: a search which it is wise to understand as an intellectual gymnastic, but whereon nothing practical, real, or true can be built" – a curious anticipation of Arendt's (1978) recognition that philosophy and common sense are often at war with each other. His statement should stand, rather, for the attitude that we usually understand by the term common sense itself, an attitude that demands conformity with what seems to be obvious (Miceli, 1982: 583) – in his case, the evolutionary superiority of the Western intellect, impatience with its more pedantic manifestations, and an agnostic stance toward religion. Indeed, Harrison's argument represents only a slight retreat from the most extreme manifestation of *le bon sens* in the eighteenth century, when some writers, paradoxically and rather contemptuously countering what they perceived as the opinion of the masses, saw it as a validation of atheism (Rosenfeld, 2011: 118–128).

Reason, in those earlier phases of Western thought, was attributed an existence and a purity that raised it above the heedless assumptions of common belief; it was actively opposed to common sense and exempted from cultural specificity (Arendt, 1978). The idea that any form of reason must itself have been historically and culturally contingent – that it

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12039-2

was a form of common sense – would have scandalized both these writers and their Victorian successors such as Harrison. It may still offend many who begin their arguments with phrases like 'it stands to reason' – phrases that often turn out to be straightforward appeals to the idea of a universal common sense. In this respect, modern religious antirelativism (see Remotti, 2008) often comes remarkably close to the authoritarianism of the eighteenth-century atheists as well as to that of some currently popular models of 'rational choice' (on which see Tambiah, 1990: 119–120) – but the similarity is enabled by widely divergent views on what constitutes common sense itself. This example alone suffices to show why a universalist understanding of common sense simply does not work. No anthropologist today would accept the argument that reason is independent of context – the position that Arendt identified as a characteristic of most of the history of Western philosophy.

A comparative approach recognizes that the obvious, or, in Douglas's (1972) terms, self-evidence, is only obvious or self-evident from an insider's perspective; the obviousness itself is constructed and contingent. To the exponents of any claim of obviousness, in any given culture, it stands to reason that the self-evident requires no further inquiry – exactly the attitude expressed by Harrison. When two versions of common sense collide, however, as in Pope Benedict XVI's attack on relativism and the anthropologist Francesco Remotti's (2008) reply invoking the cultural specificity of the forms of common sense, that specificity – famously described by Antonio Gramsci (see Bates, 1975) as the conceptual realization of hegemony – may become manifest; but it will only do so if one is willing to take a relativistic position even toward relativism itself. In short, the approach requires particularistic methodologies; it is in the detailed examination of how common sense is actually used that its cross-cultural inconsistencies are revealed.

Historical research and ethnographic fieldwork thus offer the most promising paths to exploring these specificities and resisting the seductive generalizations that they generate. In the realm of politics, it is the polemical use of the term 'common sense' that shows us, if we can suspend our partiality in the actual dispute at hand in any given context, how its meanings respond to the ideological and political demands of specific situations. Anthropologists' preferred method of ethnographic fieldwork is especially well suited to decoding the underlying assumptions of local forms of common sense. This is because anthropologists are constantly surprised by unfamiliar assumptions of this kind; these often conflict with the scholars' own assumptions about what is 'natural.'

Most anthropologists tell stories about moments of sudden insight; they are almost always about revelations of different kinds of common sense. When I first asked the shepherds in a mountain village among whom I was doing research why they stole sheep from each other (Herzfeld, 1985), for example, they argued that they did so in order to gain each other's friendship. I was initially nonplussed but intrigued. For their part, the shepherds managed to convey the distinct impression that I was not grasping something self-evident, obvious, and, indeed, commonsensical. Their reaction was one of amused astonishment that I could not understand that a tough man had to display his toughness in this way if he wanted to create alliances with other shepherds (Herzfeld, 1985: xiii, 174–183).

Their response was reminiscent of Evans-Pritchard's (1937) Zande informants' reactions to his initial failure to grasp why the collapse of a granary on a man's head was not the result of termite damage alone but must have entailed witchcraft for it to have happened at that particular moment; the explanation was determined by the social circumstances of the event. That example has led to heated debates about the extent to which non-Western people can be said to possess a conceptual framework compatible with the production of scientific thought (Crick, 1976: 121; Tambiah, 1990: 130–139; Winch, 1972: 8–49). What did emerge with clarity from these debates is the realization that logic is not the prerogative of any one cultural tradition or even educational level – a point that was paralleled within the Western world by Labov's (1972) remarkable demonstration of some scholars' inability to recognize logic in statements by young urban African Americans in which the ideas were not structured according to scholarly criteria of syntax and precision.

The anthropologist's first task in the field, as these examples illustrate, is to understand why an apparently meaningless explanation 'works' for local people – why, in other words, it satisfies their criteria of common sense. The explanation may be a straightforward question of translation, but it more frequently resides in different perspectives on what constitutes common sense. In Crete, I was confronted by the question of how to decode a logic (we have to steal if we want to have friends) that seemed obvious to my respondents but was initially opaque to me. When it became apparent that in their tough environment these men needed assurances that those with whom they allied themselves were reliably fierce and agile, it began to make sense that they would introduce themselves by carrying out a raid. It also became clear to me that I was adjusting my own ideas about common sense. I had been trained to do this, to be sure; but the experience, especially in such a dramatic context, produced a momentary sense of dislocation from the safe moorings of the familiar.

That insight, moreover, was probably the starting-point of a much more general reflection that eventually led me to characterize social and cultural anthropology as the comparative study of common sense (Herzfeld, 2001: 1). That characterization – which also contributes to Remotti's defense of relativism – is admittedly somewhat tongue-in-cheek, but it has the advantage of laying out clearly the key challenge, that of convincing practitioners of the other social sciences that obviousness, like boredom (Herzfeld, 2004: 117–120), is inherently worthy of study – "precisely because," as Miceli (1982: 583) remarks, "all cultural objects actually presuppose a point of view about reality and impose it, tacitly, through the simple fact that one uses it and learns to understand its significance and usefulness." How this comes about, moreover, is a central issue for the analysis of power. Why are some things obvious, and to whom, and who has an interest in maintaining that state of affairs? (With boredom, the corresponding questions are those of why boredom should be interesting and what it conceals from other social actors.) How, in short, is obviousness used to maintain or subvert dominant ideologies?

The investigation of these questions requires a very personal commitment to the analysis, since the ethnographer's own version of common sense is a key element in the comparative

exercise that ensues. A relevant aspect of anthropological reportage that sets it apart from the conventions of most other social sciences is the use of the first person in accounts of research. Anthropologists thereby seek to restore agency to their own intellectual endeavors and so to undermine the claims of immunity to challenge that assertions of common sense typically entail. At the same time, this insistence on foregrounding their own presence has methodological consequences that are especially important in investigating common sense – a property they may ostensibly share with their informants while then discovering that in fact their respective understandings of it are quite divergent.

Thus, for example, Lilith Mahmud (2013: 6, 36–37, 43–45), in her fieldwork on female Freemasons in Italy, gained traction by addressing her own presuppositions in the same frame as those held both by her informants and by the larger Italian public. She confronted three sources of common sense. First, as an Italian, she discovered that her own African appearance conflicted with what her informants automatically assumed about how Italians should look. Second, she also discovered in herself significant traces of official attitudes, replete with conspiracy theories, toward the entire Masonic phenomenon. Third, her own surprise at discovering that there were female Masons eventually morphed into a vibrant field experience. Using her own positionality as a *comparandum* proved to be an invaluable tool for disinterring a range of assumptions, including some she had originally shared with many other Italians, and making them an object of analytic interest.

The particular value of ethnography and archival work in exploring the variability of common sense lies in the focus of both methods on well-contextualized detail. Precisely what we mean by context varies, however, so that, from an anthropological perspective, some ethnomethodologists' emphasis on the context of particular conversational situations (e.g., Garfinkel, 1973) may seem too narrow, while philosophers' analyses – even when historically grounded (e.g., Ledwig, 2007: 122) – make little use of context and often appear to dismiss it as trivial. Anthropological research on common sense, by contrast with both these tendencies, ideally seeks to link vertically differentiated contexts (e.g., national and community levels) and thereby show how the assumptions made in the name of common sense work in practice to create a sense of common identities based on shared ideas. It is by focusing on use, rather than only on form and definition, that we may be able to rescue the concept of common sense from its taken-for-granted relegation to the background of both research and everyday politics, and this is consistent with anthropologists' preference – itself the outcome of their commitment to fieldwork – for use or action theories of meaning over more static concepts of reference (see Crick, 1976, for an early exploration of this issue).

A useful starting-point for any investigation of how common sense is used may be found in the work of the sociologist Alfred Schutz. Schutz's insistence (1973: 18) that "the pre-scientific vernacular can be interpreted as a treasure-house of ready-made pre-constituted types and characteristics, all socially derived" describes precisely what should attract the attention of social scientists in the very idea of common sense. True, there is an unfortunate hint of evolutionism in Schutz's invocation of a 'prescientific vernacular;' Gupta (1998: 172–179), in particular, has exposed the commonsensical Western assumption that 'indigenous' and 'scientific' conceptual worlds are separate and unrelated, showing thereby that the forms of common sense we encounter in the field may have multiple (or hybrid) sources, although they tend today to be hierarchized in accordance with residual ideas about the superiority of the 'scientific' over the 'folk.' But Schutz's insight into the socially constructed nature of common sense does not require us to adopt a similarly evolutionist stance, and it does allow us to track the emergence of ideas of common sense and to trace their realizations as various kinds of classification back to their social roots in specific activities and experiences. In this way, Schutz especially paved the way for Mary Douglas's (1966, 1970, 1972) seminal contributions to the analysis of self-evidence and its relationship to taxonomy.

Schutz's was thus a vital move, since one of the more obstinate problems is the insistence of most forms of common sense that there is nothing to analyze. Common sense as a concept suffers from the paradox of parochial universalism. Every village holds that its version of common sense represents a universal truth (and anthropologists are often upbraided by their informants for asking questions about things that are deemed too obvious to merit discussion); some areas of Western scholarship have, *mutatis mutandis*, done much the same. But all claims of common sense, scholarly ones included, emerge, as Schutz argued, from ordinary practices and successful repetition. If a particular version of common sense seems to work, this is because it inevitably rests on a presumption of universal truth grounded in very particular local practices and experiences.

The utility of any version of common sense to the ends of power lies in the ease with which the reality of its context-dependency can be concealed – and often is concealed, for political reasons that animated Gramsci's widely acknowledged reading of common sense as hegemony. Indeed, while – for example – some bank economists are active in creating public understandings of what constitutes common sense, as Douglas Holmes (2013) argues, it is only when we see these economists as anthropologists trying to unravel a specific cultural problem that we realize how situation-specific their current version of common sense actually is. Their actions exactly parallel those of professors and bureaucrats, for example, who pronounce that something 'stands to reason.' The performative force of such declarations (Austin, 1975[1962]) occludes the fact that they have a history, one in which they have been brought into being to express a particular ideology or worldview. If Holmes is right about the economists, whose discipline certainly does have a highly variable history of engagement with ideas of common sense (Coates, 1996), in recent years they have worked to achieve general acceptance for a very particular and highly self-interested perspective, while making that perspective seem, like any nationalism, to be an eternal, universal, and *discovered* verity, rather than a contingent, local, and *invented* opinion. With Gramsci, but with more ethnographic specificity, Holmes shows exactly how people's complicity in their own cooptation is engineered in social practice.

If ethnography allows us to disabuse ourselves of the universal validity of any version of common sense, a diachronic perspective helps us to disinter the cultural and historical

accidents on which the assumption of a universal common sense usually rests. Even from a short-term perspective, we all know from personal experience that what seemed bizarre at one point in our lives has been naturalized as common sense; this is as true, moreover, for our own theories, methods, and writing practices as it is for ordinary actions and policy decisions (see Klein, 2006: 1158). Sophia Rosenfeld (2011) generously acknowledging that the decoding of common sense has been especially the focus of anthropologists such as Clifford Geertz (and therefore primarily synchronic in focus), nonetheless wisely argues that a historically grounded examination of the uses of the term and concept is no less necessary. As she remarks, when common sense is examined historically we see immediately that its tenets are "culturally and temporally variable in content" (Rosenfeld, 2011: 15). Comparison can be cross-epochal as well as cross-cultural; given the chronological depth of the concept of common sense, tracing its translation into various languages and the recorded shifts in meaning in each such language is no less necessary than a consideration of what makes sense to our contemporaries in different societies.

In fact, transposed onto a historical plane, Geertz's (1983: 75) perspective offers an enhanced insight into why common sense so often appears to have the authority of doctrine, sometimes explicitly so ('God-given truths'): "Religion rests its case on revelation, science on method, ideology on moral passion; but common sense rests its [case] on the assertion that it is not a case at all, just life in a nutshell. The world is its authority." Precisely so, but that world (Greek *kosmos*) is itself ground to the figure of cosmology or religion. And the world is not experienced identically, even in the most ordinary of sensory domains (such as sight), in exactly the same way in every social group. The apparent inability of the Abelam people of New Guinea to make sense of a two-dimensional photograph as the representation of a three-dimensional person (Forge, 1968) is no stranger than the similar inability of Western anthropologists to understand why a pattern of lines and squiggles provides an iconic representation of deity – or, for that matter, why one has to steal sheep in order to create new friendships. Geertz understood that common sense was always self-referential: one appeals to common sense in order to justify common sense. That understanding rests on a more radical proposition: that the circular source of the self-confidence we call common sense requires a blissful unawareness – willful or not – of the contingent nature of the ground itself.

Appeals to common sense are inherently political, in at least two important ways. First, they rest on a hegemonic form of understanding; this was Gramsci's great contribution to the way we conceptualize common sense today. Second, common sense is often viewed as the basis of notions of rationality in government; rational choice models rest on such an argument since they usually assume that what constitutes a rational choice is determined by economic and political factors rather than, in part, by cultural values.

The political aspect of common sense has not yet been a major focus of anthropological research; it does not get much of an airing in Geertz's work, for example. This may be about to change, particularly as a burgeoning anthropology of Western societies 'exoticizes' many forms of obviousness. Nonanthropological discussions of the role of common sense in politics, for example, tend to revolve around its relationship to the demarcation between democracy and populism (e.g., Arendt, 1958; see also Rosenfeld, 2011), whereas an anthropologist would typically ask *how* claims of democratic process, transparency, and social justice were being used in everyday practice. One interesting exception to the general pattern is the work of the political scientist Michael Connors (2003: 17) on what he calls "democrasubjection" – "the subjection of people to imaginary forms of their own rule." Connors's analysis, which sought to decode the tactics of former Thai Prime Minister Thaksin Shinawatr (but perhaps applies equally to his self-proclaimed democratic opponents) is nicely paralleled in anthropology by Rosalind Morris's (2004) dissection of the uses of 'transparency' to produce its exact opposite – especially in the form of the concealment of favor-peddling – during the same phase of Thai political history. While neither of these authors specifically addresses common sense as a concept, their analyses, although coming from radically different intellectual traditions, are striking for their convergence in addressing how political rhetoric can exploit commonsensical assumptions and so hide the operation of power.

These studies stand in stark contrast to Arendt's (1958) claims for common sense as the basis of true democracy. Her argument seems to assume that a freely sought consensus will always favor the interests of the majority. Her position, however, ignores the historical evidence that, in democratic systems, electoral majorities often demand policies that entail the persecution of minorities, and it assumes that the shared assumptions of the majority necessarily guarantee the happiness of even those who strongly disagree with the majority view (see also Rosenfeld, 2011: 254–255). The thinker who recognized the banality of evil seems to have overlooked the dangers lurking in the banal.

Moreover, the banal, as Billig (1995) has demonstrated, is the means through which ideologies such as nationalism *become* common sense. These ideologies assert that common sense will automatically show the way to social improvement: "What Georgia as a country needs is a culture of common sense. Nothing would develop this culture better than fostering a habit of basing judgments on facts, rather than on 'values' or political agendas" (Nodia, n.d.). But who is to direct such changes? How will their fairness be guaranteed, and who sets the agenda for, and definition of, fairness? Such positions entail an abdication of agency at exactly the moment at which they appear to embrace it.

Statements of this kind illustrate the process that Bourdieu and others have recognized as the naturalization of culture: "It is because subjects do not, strictly speaking, know what they are doing that what they do has more meaning than they know. The *habitus* is the universalizing mediation which causes an individual agent's practices, without either explicit reason or signifying intent, to be none the less 'sensible' and 'reasonable'" (1977: 79). What goes for individuals goes, a fortiori, for entire social groups, and it is inevitably a political process in the broadest sense. It is for this reason that anthropology's commitment to the analysis of the particular and especially of the details of the relationship between agency and social order

and change makes it an especially salutary basis for a critique of common sense.

But this is also a reason to be very cautious about giving it the status of theory. While our informants *do* theorize, and sometimes in terms that we can recognize as such (Herzfeld, 1985; Labov, 1972), and it is important to recognize that capacity, their theoretical observations are less a matter of what they regard as common sense than they are of carefully considered positions not unlike those of the scholars who study those societies. Unreflective assumptions offer no more analytical advantages in their social lives than they do in our scholarly pursuits. Dunnell's (1982: 12–13) treatment of common sense as an adaptive mechanism, however, suggests that for him it had an evolutionary function, and that this is what invests it with universal value even as we recognize its internal variability. But that argument is itself an appeal to a common sense that while it has remained popular in the media, is no longer universally entertained within anthropology.

Thus, I prefer to argue for a critical deployment of analyses of 'common senses' (a phrase already used by Dunnell) as a counterpoint to the ethnocentric assumptions he rightly identifies as underlying a great deal of commonsensical theorizing – what goes for archaeology is also true for other branches of anthropology. Some may wish to expand that use of common senses still further, arguing for a distinct anthropology of common sense. But anthropology has long been committed to the decoding and comparative analysis of everyday phenomena, and, as such, the discipline has necessarily been at its very core a critique of the claims – the many claims, to be sure – of whatever is locally or globally upheld as common sense. There thus seems little advantage in trying to create a special area or subfield; indeed, doing so would probably reduce anthropology's traction among the social sciences in general, and diminish its relevance to public debate as well. Especially now that some values, including common sense, appear to be gaining a new purchase on universal validity, the particularism of anthropology as a discipline offers a necessary and lively resistance to their sedimentation in some ethnocentric but allegedly global hierarchy of value.

Communalism

Peter van der Veer, Max Planck Institute for the Study of Religious and Ethnic Diversity, Göttingen, Germany

Abstract

Communalism refers to communities of belonging and especially to such communities in Indian society. More specifically, it refers to the articulation of religious communities into mutually antagonistic, social, political, and economic groups. It emerges within the context of the colonial modernization of Indian society, in which the Indian population was classified, counted, and measured in terms of community. Communalist ideologies emerged in India in the Hindu, Muslim, and Sikh communities. Today they are connected to forms of transnational community.

The concept of 'communalism' is based on that of 'community' and has to be understood in relation to the concepts of 'nation' and 'civil society.' Communalism signifies a politics of belonging that does not emphasize the nation in all its diversity, but the homogenous, religious community. It should be clear that the term communalism comes up as an alternative to nationalism, both in theories that explain the failure of the nation-state to emerge in certain parts of the world and in theories that explain the demise of the nation-state under conditions of globalization. Like the use of the concept of 'tribalism' in the study of African politics, 'communalism' is primarily used in the analysis of Indian society and politics and is seldom encountered in theoretical arguments of a more general nature. In the present era, theories of the decline of the nation-state emphasize the possibility of transnational, virtual communities that depend on new communication technologies. The extent to which these communities articulate a politics of communal belonging that is not territorially bound is striking.

The concept of 'communalism' derives its meaning from arguments about the place in modern society of communities of belonging. According to liberal, political theory, communalism is based on primordial attachments and stands in the way of the formation of a modern, civil society, in which individuals act as equals on the basis of their allegiance to the state in which they enjoy the rights and duties of citizenship. In modernization theories, communalism signifies a hybrid phase between traditional society and modern society, since it combines modern democracy with political mobilization of religious communities in a plural society. Such theories make a sharp distinction between secular nationalism on the one hand and communalism on the other. Inherent in all these theories is an opposition between religion, seen as part of traditional society, and secular modernity. The fact that religious communities form a strong political force in modern societies all over the world cannot be understood in terms of standard modernization and secularization theories.

Communalism then signifies a politics of belonging that does not emphasize the nation in all its diversity, but the homogeneous, religious community. It resembles the current notion of communitarianism in that it refers to a political agenda of communicative interaction within a particular community on the basis of shared 'habits of the heart,' but rather than emphasizing the defense of a 'common way of life,' it is much more aggressively antagonistic toward other, similar communities. It should be clear that the term communalism comes up as an alternative to nationalism, both in theories which explain the failure of the nation-state to emerge in certain parts of the world and in theories which explain the demise of the nation-state under conditions of globalization.

'Communalism' is primarily used in the analysis of Indian society and politics and is seldom encountered in theoretical arguments of a more general nature. It refers to the articulation of religious communities into mutually antagonistic, social, political, and economic groups in India. Again, like 'tribalism' in Africa, communalism in India has a history as colonial theory with great social and political consequences. It emerges in the context of the colonial modernization of Indian society. The Indian population was classified, counted, and measured in terms of community. Notions of caste and religion were crucial in the census operations which took place on a regular basis from the 1870s. British colonial policies were strongly influenced by essentialist assumptions about the nature of Hindus, Muslims, and Sikhs. In their system of governance, the British sought alliances with the 'natural leaders' of communities and, ultimately, this created a system of representation in which membership of a community took precedence over place of residence. Recruitment for jobs both in civil administration and in the military was also organized around notions of race, caste, and religious community. The notion of 'martial races' was specifically applied to the Sikhs, a religious community in the Punjab, North India. The British recruited only 'pure' Sikhs who were following the strict norms of what the British considered to be the proper Sikh faith. In this way, the Sikhs became a dominant section in the Indian military until today, and a particular 'orthodox' form of Sikhism was promoted with great social and political consequences for the region.

The extent to which language politics was influenced by colonial ideologies of communal difference was also important. The medium of communication was supposedly related to communal identity. A major issue was the question of whether Hindi or Urdu should be the language of instruction and the language of government besides English. In the debates about it, Hindi came to be conceptualized as the

language of the Hindu community while Urdu came to be conceptualized as the language of the Muslim community. In the later part of the nineteenth century, Hindu leaders increased their attacks on Urdu and Indo-Persian culture by emphasizing the communal basis of the differences in script and vocabulary between Hindi and Urdu. A new vernacular literature emerged which attacked the joint Hindu–Muslim culture, as expressed in Urdu or the spoken vernacular, Hindustani. The principal arenas for the Hindi–Urdu controversy were schools and entry exams for government service. After the Partition of 1947, Urdu became the national language of Pakistan and Hindi, besides English, the main administrative language of India. The identification of language with religious community was also the ground on which the Sikh community after Independence started to demand a special status for the language of their sacred scriptures.

The legal structure of both colonial and postcolonial India has been greatly influenced by the notion of communal difference. Colonial law was grafted on Hindu and Muslim legal traditions which were interpreted and codified in a joint effort of British legal scholars and native religious specialists. Ancient Sanskrit texts, for instance, became foundational for the creation of Hindu civil law. Personal law in India until the present day is based upon communal difference. The contradictions between the claim that India is a secular state and the existence of communal laws can be briefly illustrated by the Shah Banu conflict of 1985. Shah Banu had been divorced by her husband according to Muslim customary law in 1978, but obtained alimony on the basis of a general criminal law against vagrancy. Her husband appealed to the Supreme Court arguing that Muslim law did not require him to pay alimony, but the court rejected that argument in 1985 with the further comment that the government should draw up a uniform civil code. Muslim organizations quickly responded to this judgment with countrywide agitations, claiming that Muslim personal law was in danger. The then Prime Minister, Rajiv Gandhi (1944–91), gave in to their demands and overturned the Supreme Court decision by making a law which would no longer require a Muslim husband to pay alimony. This in turn was taken up by Hindu communal organizations which objected against the government's pro-Muslim stance, as well as by secular feminists who saw the government action as male chauvinism.

Communalist ideologies emerged in India in a variety of forms during the twentieth century. In the 1920s, V.D. Savarkar (1883–1966) published a book which connected Indian territory with Hindu identity and thus formulated a communalist ideology that made Muslims, Christians, and others into outsiders, at best second-rate citizens. His thoughts continue to play a significant role in the ideology of the Rastriya Swayamsevak Sangh (RSS), the leading Hindu communalist organization founded in 1925. This organization and its many branches are active in trade unions, political parties, and religious organizations, but it primarily tries to train young men in a military fashion to 'defend the Hindu nation.' The RSS has often been at the forefront of political violence against Muslims and Christians, before and after Partition. It was the driving force behind actions to demolish a sixteenth-century mosque in the Hindu pilgrimage center Ayodhya in 1992, an event which made the political party with which it is connected into the leading party of the country.

On the Muslim side, it is the Muslim League and the Jama'at-i-Islami which are, historically, the major communalist organizations. The Muslim League's demand for a separate homeland for Muslims in the early 1940s began the political process which led to the Partition in 1947. The poet Muhammad Iqbal had formulated the wish for separation in his writings, but his main influence had been on Muslim students both in India and abroad. It only received political significance in the 1940s when Jinnah (1875–1948), the leader of the Muslim League, took it up. The speed with which the separationist movement gained support demonstrates the extent to which the political and social system in India was conducive to the communalist articulation of religious difference in India, with immense political consequences until the twenty-first century. The complexity of Muslim communalism can be demonstrated by the fact that the founder of the most militant Muslim organization in South Asia, the Jama'at-i-Islami – and as such the counterpart of the Hindu RSS – Maulana Maududi (1903–79), was in principle against the formation of Pakistan. Partition, however, forced Maududi to move to Pakistan, where his organization became a redoubtable political force in campaigns for an Islamic constitution and laws against un-Islamic practices. His revolutionary ideology had a great influence on the Muslim brotherhoods in Egypt and the Sudan.

Another major communalist development in India is the emergence of the Khalistan movement among Sikhs. Sant Jarnail Singh Bhindranwale (1947–84), a young religious leader, created a large movement, popular largely among the urban youth, demanding a separate state for the Sikhs, Khalistan. It was repressed by the Indian army in 1984. The movement can be partly explained in terms of an identity politics in which Sikhs try to maintain the symbolic boundaries which divide them and the surrounding Hindu majority. These symbolic boundaries, such as the wearing of uncut hair and turbans for men, are only maintained if they are supported by the fact that Sikhs derive material gains from their membership, as they clearly did in the colonial period. The political and economic aspects of membership are intrinsic to the religious ones and it is therefore not useful to understand the Khalistan movement as either a religious or a political movement. It is like the Muslim and Hindu movements, a communalist movement which articulates the religious community in a political and economic way.

In the twenty-first century era, theories of the decline of the nation-state emphasize the possibility of transnational, virtual communities which depend on new communication technologies. The extent to which these communities articulate politics of communal belonging that is not territorially bound is striking. This form of transnational communalism enables a politics which simultaneously connects very diverse issues in very different politics. The best example of this has been the so-called Rushdie affair, which started with the banning of the novel *The Satanic Verses* by the Indian government in 1988 under pressure from Muslim communalist leaders. This was quickly followed up by demonstrations, organized by leaders of 'the' Muslim community (mostly Indian and Pakistani) in the United Kingdom, and then followed by a call for the

execution of the author by the self-proclaimed leader of the Muslims, the Sh'ite cleric, and leader of the Islamic Republic of Iran, Khomeiny. The use of the notion of community in these political actions is widely varied, but simultaneously it allows some sense of unity across the globe. It is strongly tied up with migration to the North by members of religious communities and thus with minority politics and secularism in the countries of immigration. At the same time, it is engaged in communalist projects in the countries of origin, where these communities might constitute the majority, as indeed Sri Lankan Buddhists, Indian Hindus, and Pakistani Muslims do. It is this kind of transnational communalism, strongly supported by new media, which will become more important in the current era of globalization. This should not be understood as the defense of primordial attachments in the face of modernization and globalization, but as completely new forms of community and identity politics.

Abstract

This article treats, with few exceptions, ethnographical studies of communes. By 'communes' is meant relatively small collective communities that typically regard themselves as alternative to their ambient social orders. Although these communities lend themselves well to ethnographic research, anthropologists have not shown great interest in them. The most notable and substantial ethnographic studies focus on North American Anabaptist settlements (the Hutterian brethren), the Israeli kibbutz, and Japanese communes. Taking their cue from the self-proclaimed alternative character of communes, these studies tend to focus on the institutional and psychological difference collective social arrangements make, and on the ability of the communities to cope given an adverse social surround. The resulting analyses of the tension between collectivist theory and practice, and of the nature of collectivist commitment, are both informative and provocative. But the evident tendency to take as guiding sociological problems, the 'social problems,' in terms of which these communities worry and busy themselves seems to grant too much to the ideological presumption of 'alternative' and to overlook the anthropological advantage of a research perspective gained from the disciplined study of 'other cultures.'

For purposes of anthropological investigation, 'commune' may be taken to refer to relatively small communities, which have set themselves up, typically self-consciously, as alternative to the wider social order, and embrace collectivism in some substantial fashion. They tend to be small enough to operate principally by virtue of face-to-face relations, they are inclined to hold resources and property in common, and usually, they favor communal decision making for political purposes. This article treats the study of such communities by, especially, professional anthropologists or ethnographic researchers.

'Alternative' Communities

The great bulk of social and humanistic science research on communes may be found in the disciplines of history, sociology, and psychology. Anthropological studies are relatively few in number, and only one small book treats communes as a general topic (Hostetler, 1974b). Considering that communes have much in common with the sort of small-scale community that anthropologists have preferred to investigate, it is curious that these scholars have not shown more interest in them. Like village communities, communes lend themselves to the kind of intensive fieldwork diagnostic of ethnography, and are especially accessible to the anthropological aspiration to research communities in the whole.

Perhaps one reason for the relative lack of anthropological attention is the consideration that in the social science literature, communalism has been largely associated with Western social settings. Whereas anthropology has focused on 'other cultures,' most (but not all) communes are not *other* in the relevant sense. They characteristically present themselves as essentially *alter*native to the societal orders in which they arise. However, in the present connection, significantly, the otherness entailed by such alterity can be misleading. For, as inverse and, in part or whole, utopian reactions to the dominant social order, such communities share with the latter rootedness in the same body of social thought. In the West, this body of thought revolves around the question of the relationship between society and the individual, especially when that relationship is apprehended as a dualism. Seeing the dominant social order as primarily individualistic, communal societies propose to resolve the dualism to the contrary, by creating social and cultural conditions that ensure the valuational primacy of the collective over the individual. Typically, the realization of the primacy is keyed to institutional mechanisms that move the individual to grasp his or her self-identity primarily in terms of the collective.

Anthropological and Ethnographic Studies

The most notable and substantial ethnographic studies of communes pertain to three different communal social settings: North American Anabaptist settlements, the Israeli kibbutz, and Japanese communes. Typically these studies take their cue from the presumptively alternative social nature of their subject, and accordingly tend to feature the way in which collectivism affects 'normal' institutions and practices, and the capacity of the community to withstand the opposing pressures of the surrounding social order.

The Hutterian Brethren

Hostetler's work on the Hutterites is exemplarily anthropological, distinguished by its ethnographic comprehensiveness and depth of cultural knowledge. He studied this people over a period of several years, and his publications (see especially Hostetler (1974a) and Hostetler and Huntington (1996)) provide rich descriptions of the 500-year history of the Hutterites, their worldview and critical system of Christian belief and practice, the colonies' economic, political, and domestic organization, and the difficulties experienced by this people in sustaining their unique communal way of life. But the principal focus of his research is socialization. Given the long-term survival of this social order under presumptively

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12041-0

adverse external societal and cultural conditions, Hostetler supposed as the key to this evident success the inculcation of cultural values. Accordingly, he set out to examine the Hutterite child rearing system. He finds that the system of socialization is remarkably effective for reasons of its ideological certitude, utter consistency, and understanding attitude toward modest forms of individual deviancy.

The system is predicated on the Christian belief in the absolute authority of God and the presumption of the primacy of communal order as the key to ensure the submission of the will of the individual self to the will of God. Human nature is seen as dualistically divided between carnality and spirituality. The former quality is understood as in need of firm submission to the latter, a condition meant to be realized by means of communal existence. All the institutional practices of the Hutterites, including, of course, the education and training of children, are designed to function strictly on behalf of this spiritual principle of hierarchical authority. In result, Hostetler concludes, the Hutterite's sense of individual self is only weakly distinguished from his social identity and is predisposed to self-denial and obedience to authority. In view of this analysis, Hostetler (in line with Hutterite opinion, and perhaps tautologically) is inclined to explain defection as a product of aberrant circumstances in which individuality emerges as an unruly force. These circumstances are, he suggests, associated with undesirable competition among family lines and the failure of these families to truly subject their autonomy to the social whole.

In his substantial monograph on the Hutterites, John Bennett (1967), like Hostetler, is interested in how this order of communal life perdures and maintains its traditional integrity, given the contrary nature of the surrounding social environment. But instead of socialization, Bennett focuses on the agricultural economy of the colonies and the impact of technological development. In line with the general tenor of Hostetler's account, he argues that for reasons of their sure sense of identity, extremely efficient management, well-formed social order, and rational approach to economic matters, these communities are exceptionally adaptable. More particularly, because they are very open to technological change but not to consumeristic influence, they are enabled to thrive without corrupting their traditional way of life.

Zablocki's philosophically rich study of the Zablocki (1971), another deeply religious Anabaptist community, less traditionalist than the Hutterites, also constitutes an important contribution to the anthropology of communes. Zablocki is a sociologist by training. But by virtue of his intensive fieldwork in a single settlement, and his attention to the quotidian course of social events, his study is patently ethnographical. He, too, was interested in the relative success of the Bruderhof. He addresses this issue in terms of 'commitment,' a notion pertaining to the fusion of self-interest with the needs of the community and given currency in Kanter's *Commitment and Community*, a sociological study (contemporary with Zablocki's) of communes in general (Kanter, 1972).

In addressing the question of the manner in which the Bruderhof manages to create and sustain the commitment of its members, Zablocki takes, in addition to the standard functionalism of Hostetler's and Bennett's work, a strong psychodynamic turn. Unlike Hostetler, whose approach to the question of commitment typifies the 'culture and personality' school of interpretation, Zablocki draws on psychoanalysis in a way that bears directly on sociological dynamics, not personality. His main finding is that the Bruderhof is characterized by an institutional structure the critical function of which is to call on and employ the ordinarily repressed psychodynamic energy of collective behavior in order to sustain commitment. Hence, when the community suffers a social crisis that threatens commitment on the part of members (such crises are, he finds, inevitable), this structure of resolution – a joyful prayer meeting of the whole – is brought into play, revitalizing commitment. In effect, he depicts a community keyed to something like Rousseau's 'general will' (a concept of 'commitment' if ever there was one), the difference being that in the Bruderhof this will is regarded as accessible (it is thought to preexist its concrete determination) only by means of the realization of a spiritual rather than rational or political unity. By arguing that this spiritual unity is brought about through collective behavior and affective effervescence, Zablocki charges Durkheim's famous but vague sociological thesis, about the transcendent force of society, with a determinate psychoanalytical dynamic.

Underlying Zablocki's concern for commitment is a more general concern about the relation between community and freedom. This concern is of interest to him for reasons beyond the question of the Bruderhof, as he finds that American society, in general, suffers from a need for community. Hence, for him the examination of the Bruderhof carries lessons for the society at large, the most prominent of which is the importance of distinguishing a kind of freedom that is nonindividualistic.

The Israeli Kibbutz

Melford Spiro's first book on the kibbutz (1970) continues to serve as an anthropological introduction to this well-known communal society. It presents usefully and clearly the community's historical beginnings, ideological principles, and institutional organization and practices. It was originally intended to serve as a preliminary chapter to the book resulting from Spiro's basic research project on the kibbutz, namely, a study of socialization and personality development (Spiro, 1965). Like Hostetler on the Hutterites, Spiro was intrigued by this communal enterprise's goal of recreating man in society's image, making him truly fit to live in social harmony (the kibbutz ideology's hoped-for 'New Man'). And like Hostetler, Spiro approached this problem as a question of the causal relationship between culture and personality, presuming that the personality of the founders' children must take its shape from the social arrangements fashioned by the parents. In particular, seeing the goal of communalism as essentially incompatible with conflict and hostility, Spiro sought to determine the degree to which kibbutz socialization and its system of 'collective education' were successful in eliminating the 'aggression drive' in the children reared in this way. This is the research theme around which centers his psychologically expert study *Children of the Kibbutz* (the title is an expression of a kibbutz ideological shibboleth), the major product of his research on this community (Spiro, 1965). As a result of his inquiry, he finds what he already anticipated in the epilogue of his first book on the kibbutz and is consistent with his

penchant for basic psychoanalytical theory that aggression, being a universal drive, can be curbed but not eliminated.

Spiro's psychoanalytical naturalism receives even greater emphasis in his later study of women in the kibbutz (Spiro, 1979), a topic presenting itself in light of the ideological aim to establish equality between the sexes. Here he concludes, unequivocally, that gender role differentiation is due to 'precultural' factors and therefore not subject to cultural elimination. In point of fact, the direction of Spiro's explanatory exercises was signaled, even before the publication of his first volume on the kibbutz, in a provocative article (1954) the thesis of which is that the kibbutz had managed by cultural design to do away with the family in favor of the undiluted integrity of the collective whole. A few years later, however, retracting this thesis and foreshadowing his naturalistic universalism, he concluded that the family does constitute a distinct feature of kibbutz social structure (Spiro, 1960). The merits of his psychological orientation aside, Spiro's work on the kibbutz is astutely and invaluably attentive right from the start to the stream of social problems that bear on the place of the individual and run steadily beneath the ideological and even empirically minded self-presentation of this communal society.

In *Two Kinds of Rationality*, Evens (1995) treats the question of liberalizing change in a kibbutz in relation to democratic procedure and generational conflict. His phenomenological emphasis on practice and tacit knowledge sharply distinguishes his approach in the present connection. It leads him to look beneath the ideology for, rather than biological or psychological causes, contradictory understandings that are so taken for granted they predispose their hosts, whose self-identity cannot be told apart from these understandings, to certain behaviors. He traces the understandings in question to Rousseau's contractarian theory of the relationship between the individual and society, and then to the sense of man and generation given in the Hebrew myth of Genesis. Like other students of communal societies, Evens is moved to use his research as a basis on which to develop a theory of human conduct; in his case, one keyed to an ontology of ambiguity and a considered notion of ethics. In an earlier essay (Evens, 1975), he closely examines a case of stigmatization in the kibbutz, in order to bring into relief the deepest meanings of the most basic social position in this society, that of 'member' or *chaver kibbutz*. He found that the meanings in question betray implicit, unreflected ideological expectations of failure in the face of perfectibilism, and foster in respect of these expectations defensive but disturbing social acts.

Allison Bowes's (1989) *Kibbutz Goshen* not only serves as a sound ethnographic introduction to the kibbutz, but also analyzes prominent social problems characterizing the community in which she did her research. Problems of hired labor, competition over work roles, the reemergence of familism, the sexual division of labor, and conflict between the generations are all subjected by her to eclectic but useful and empirically substantive sociological analysis. More broadly, turning a remedial eye on the very idea of ideology, she contends that the definition of these apparently troubled social circumstances as problems indicative of failure derives in large part from a misguided tendency to see kibbutz ideology as a set of fixed and decisive principles rather than a pliable and adaptive system of values.

The problem of work roles is the focus of Israel Shepher's (1983) ethnography of a kibbutz (see also Shepher, 1980). He is concerned with the threat to the practice of equality posed by the development of permanent work roles, given increasing specialization in the kibbutz economy and the concomitant demand for expert workers. He argues that insofar as this trend is comprehensively applicable to every member, the creation of a structure of inequality based on work roles is precluded, since everyone is equally indispensable to his or her place in the labor sphere. In *Women in the Kibbutz*, Tiger and Joseph Shepher (1975) take up the question of sex role differentiation. Their aim is to use the example of the kibbutz to arrive at universal truth in respect of the place of women in society. Like Spiro, they propose a naturalism. But their argument is sociobiological rather than psychoanalytical, keyed to the concept of 'biogrammar' or the genetic transmission of behavioral characteristics.

In his *Transforming Kibbutz Research*, Reuven Shapira (2008) sets out to explain the relative decline, in recent decades, of the kibbutz movement and its democratic ideal. Taking his cue especially from Robert Michels' 'iron law of oligarchy,' in which democracy is undercut by bureaucracy and in turn the development of power elites and self-interest, Shapira locates the principal source of the decline not in the communities themselves but in their federative order. He finds that on the level of the kibbutz federations, leadership has always been autocratic rather than democratic, and that this condition has had the trickle-down effect of subverting governance, and therewith the idyllic democracy, in the individual communities themselves. Thus, for example, the kibbutz principle of rotation, whereby all positions of authority are supposed to circulate with general regularity among the members, is in practice corrupted by the influence of privileged relationships between certain members and federation leaders.

As a defense against oligarchic influence, Shapira, drawing on sociological literature pertaining to democratic work organizations, proposes an alternative system of succession to positions of leadership in the kibbutz. The principles of his system are designed to impede the development of bureaucracy, excessive conservative thinking, self-interest, and the like, by promoting trust, moral integrity, sincere involvement, and concern for the social whole. A key mechanism to implement such a system is, Shapira suggests, to decelerate succession to leadership in the hope of electing and retaining proven, good leaders. One way to do this would be, he argues, to allow reelection of creative, highly moral leaders, by requiring a higher democratic majority with each successive reelection.

While Shapira's proposals in this regard are worth entertaining, the most important contribution of his book is the argument about the perverse impact, on the kibbutz movement, of the oligarchic nature of leadership at the level of the kibbutz federations. As he emphasizes, this argument is innovative in kibbutz studies. Perhaps it could only have been realized by a qualified social scientist who is also a homegrown *kibbutznik*, a committed 'insider.'

Japanese Communes

David Plath's work on utopian communities is of special interest because it pertains to a non-Western social setting.

In a brief discussion, representative of the usual analytical focus on the struggle of such communities to flourish in the midst of contrary social and cultural conditions, Plath (1966) examines the tactics used by four different Japanese communal societies to adapt to the ambient milieu without compromising their reformatory goals. But in his perceptive epilogue to *Sensei and His People* (Sugihara and Plath, 1969), a first-person narrative of a Japanese commune authored by the wife of the commune's charismatic founder and leader, Plath identifies suggestive differences between this and Western communal ventures. He observes that, having evolved spontaneously, Shinkyo (the name of the commune) cannot be regarded as an 'intentional community,' and he brings into relief the fundamental way in which this community is continuous with, and not simply reactionary to, the ambient society. The commune got its beginnings in reaction to the formalism of Tenrikyo, a nineteenth-century Japanese religious movement related to Buddhism (Shinkyo's founder had served at one time as a Tenri priest), as well as to the 'bossism' of the local village community. But its defining emphases – moral responsibility, self-sacrifice, mutual reliance, social equality, and spiritual/bodily cleanliness – are manifestations of the traditional values of rural Japanese society. In view of the overtly complementary relationship between Shinkyo and the surrounding community, Plath's exercise suggests that this commune, though certainly radical by the actual standards of the state of things against which it reacted, practices a non-absolutist communalism. As a result, by contrast to Western communitarian ventures, the individual's identification with the social whole is not so much secured institutionally as left – not simply in the end but for all practical purposes – to the individual member's quotidian discretion.

The Russian Kolkhoz and Mao's Communes

Caroline Humphrey's (1983) social anthropological study of the Soviet collective farm or *kolkhoz* may be mentioned here but not really considered. For one thing, as a direct function of the state, the *kolkhoz* is neither alternative in the relevant sense nor self-generating. For another, although one can learn much about the social and politicoeconomic life of Soviet collectives from Humphrey's study, it is more directly concerned with problems of social change deriving from the Soviet Union's need to integrate into itself ethnic minorities (in this case, the Mongolian Buryat) than with collectivism itself. As a result, it is difficult to place Humphrey's book directly in the literature on communes, and apart from her extensive use of materials published by ethnographers and analysts native to the society in which she worked, she herself neither draws on nor mentions that literature.

In connection with state imposed and controlled communal life, it is edifying to cite the Great Leap Forward in twentieth-century China. There are now a number of works that document the dire results of Mao's authoritarian collectivization of rural China. Because it is based on two decades of face-to-face interviews with surviving residents of a village in Henan province, I cite here only Ralph Thaxton's (2008) work on the catastrophic famine brought about by Mao's utopian endeavor to accelerate China's communistic development. The resulting communes were large, each comprising as many as 5000 persons, and were characterized by forcible commitment to collectivist practice that was nothing less than comprehensive. The result of such compulsory, holistic, ideological rigidity was a monstrous unviability, by virtue of which tens of millions of people starved to death, while others were tortured and murdered by the powers that be, and still others were moved by their dreadful circumstances to cannibalize the dead.

Edited Collections and a General Sociological Study

Susan Love Brown's (2002) edited collection focuses thematically on Victor Turner's concepts of 'communitas' and 'liminality' as theoretical foundations for the study of so-called intentional communities. The collection comprises eight pieces (Brown's introduction included), by seven different contributors. The contributions vary, from an ethnographic study of an existing commune to studies of historical ones, all of which are American. The topics are mixed. To cite just two examples, there is a comparative study of identity formation in refugee camps and communes, as well as a study of a historical incident of mob violence against a Shaker community. Basically the various pieces are held together by the interest in Turner's conceptual apparatus, although one of the essays draws on Gregory Bateson's concept of schismogenesis, while another makes use of Anthony Wallace's notion of revitalization.

A more comprehensive edited collection on communal life is Kanter (1973). The volume comprises 45 articles, by sociologists and anthropologists. The articles bear on collectivist endeavors from all over the globe, and cover a great variety of problems characterizing these endeavors, such as organization, leadership, family, work, children, crises, and so on. So extensive, this collection constitutes, as Kanter suggests, an invaluable source for bringing into relief the diversity of communal enterprises as well as commonalities that serve to define these enterprises as communes.

It is provocative that in her Overview to the volume, Kanter chooses to cite Plato, in his *Republic*, as a benchmark for the utopianism she finds in communal societies. This is because, while the utopianism of the *Republic* is not in doubt, the work itself, as Kanter mentions, is remarkably authoritarian and elitist – anything but egalitarian. Plato grasped 'the people' as incapable of making good decisions and therefore in need of a ruling elite of philosopher kings to run things by deceiving the plebs. One might wonder if this picture does not conjure up an image of at least some communalists as dupes of their own ideological commitments and charismatic leaders.

For a substantial sociological study of American communes in general, Zablocki's (1980) book is impressive. Based on 10 years of sociological research, its analysis takes into account 120 different contemporary collectives, including both rural and urban ones. Its broad goal, though, is not simply to illuminate collective life but to throw light on the problem of decision making in any social order. Zablocki proposes that if reaching consensus is problematic even in a small society comprising ideologically likeminded individuals, then we can learn from the study of communes much about the difficulties of decision making in social orders in general. In effect, soberly critical of the research ethic that confounds the social relevance of a phenomenon with its sociological relevance, Zablocki focuses on the analytical

promise of sociological study of communes for societal life at large. Conceptually, he makes use of especially two notions, 'alienation' and 'charisma,' to plumb the many communes he visited. Redefining alienation as a sense of powerlessness in respect of societal decisions, and charisma as a phenomenon that serves to redress this felt impotence, he sees these two notions as reciprocal. As in Brown's and Kanter's studies, the basic issue is that of moving the individual, by means of intentional and structural conditions, to 'invest' (Zablocki's purposefully economistic usage) his or her self in the collective self. Bearing in mind here that, as Zablocki himself mentions, this study (unlike his book on the Bruderhof, discussed above) is not ethnographical, one key sociological goal of the work is to investigate the communal conditions under which a charismatic leader might arise.

Communes and the Significance of Anthropological Research

Communalism and Collective Social Movements

In light of the consideration that, given their relatively small size and considered social dynamics, communes would seem ideal sites for anthropological field research, it remains noteworthy that there has never been a major anthropological interest in them. Indeed, it might be said that today, as far as anthropology is concerned, communes have gone the way of the dinosaurs. But this is not to say that the discipline has no interest in so-called alternative social endeavors. To the contrary, driven by social activism bent on counteracting contemporary modern society, which is to say society that, whatever its formal presentation of self, effectively operates on the basis of domination and dehumanizing instrumental rationality, today's discipline of anthropology is marked by a somewhat general focus on 'social movements' (see Escobar (1992) for a formal manifesto of this disciplinary focus). To be sure, the rise of the Israeli kibbutz constituted an exemplary social movement, as did, according to Zablocki (1980), American communitarianism from the 1960s through the 1970s. But the current anthropological interest enjoys a compass that is at once much wider and for that very reason, in a significant sense, narrower than communalism per se.

Whether initiated by and for women, peasants, subalterns, gays, and other categories of persons who are made to suffer systematic injustice for reasons of their self-identity, the kind of movements in question have in today's world a global reach and relevance. By contrast to communes, which typically aim to seclude themselves from society at large, the social movements in question constitute collective endeavors to resist, dislodge, and creatively supplant domination, capitalism, and the State as we know it. When one considers, though, that nazism, fascism, totalitarianism, capitalism, religious fundamentalism (of one kind or another), and the like are also of great intrinsic interest from the perspective of doing social science, this current anthropological focus on social movements appears to be restricted to just one kind of movement, namely, the kind dedicated to the overall reconstruction of social orders as redemptively humane and egalitarian.

This consideration raises at least two critical questions bearing on the nature of anthropology as a social science. For one: *Is there any difference between doing good and doing good research?* In response to this question, it is impossible to avoid addressing the distinction between objectivism and subjectivism. And even should one hold, non-dualistically, that taking an objective stance is a subjective determination, the question retains its relevance. Thus, if it is the case that the activism of the current disciplinary interest in social movements entails the rethinking of anthropology as in itself a social movement, the primary impetus of which is to facilitate the goals and values of the movements under study, the question at issue here (one with which Weber notably wrestled) cannot but loom large. Indeed, how one answers this question has a serious consequence for the efficacy of social science research as research, even in respect of the desire to do good by aiding and abetting the movements at issue and their goals. Consider, for example, that under such a picture the findings and conclusions of social science risk repudiation as mere partisan politics. Hence, the question at issue, although at one time more or less trouble-free in light of anthropology's (erstwhile) taken-for-granted scientism, is now critically thorny.

The second consequential question I wish to pose is this: *In the sense relevant to anthropology as a social science, is the alterity that these movements are deemed to present a valid presumption?* The alternance of the movements must depend on how truly creative or original they are in their efforts to reconstruct society in protest against an inhumane social system, and on behalf of one imagined in terms of some truly liberating form of egalitarianism. For all the ingenuity this alterity exhibits, though, given the ultimately Marxian nature of the goals of these movements, it is hard to get away from the misgiving that the alterity remains a function of Western thought and understanding. In which case, as is true also of so many of the studied communitarian endeavors, the difference represented by the kind of movements at point – even should this difference register, for the time being, an actual, relative inversion of the sociopolitical status quo – continues to presuppose a fundamentally Western ontology. As a result, whatever the relative degree of their success, and however ethically estimable they are, one might still wonder if in reality these movements can transcend the ontological foundation of the social systems in which they arose, in particular the ideal of the self-contained individual. In this regard, Georg Lukács's (2010) skepticism may be excessive, but human experience and history suggest that it is nonetheless worth bearing in mind. Citing a romantic desire that arose among German thinkers at the very end of the eighteenth century, a desire to create "a new, harmonious, all-embracing culture," Lukács speaks of a "reckless naiveté," "a dance on a glowing volcano," and "a radiantly improbable dream."

Regardless of the gravitational pull of received Western ontology, anthropology, with its focused interest on so-called other cultures, demonstrates that there is a sense of alterity that supposes a 'reality' credibly different or other. It is a reality in which there is no need of *intentional* mechanisms to move the individual to invest his or her self into the social whole. This is because, innocently and in the first place, it has never occurred to the 'individual' peopling this kind of social whole that he or she is indeed primarily self-contained and self-transparent. Rather, experiencing themselves, ingenuously and predominantly, in terms of their intrinsic otherness to their selves, their

sense of individuality, although real, remains phenomenologically subject to, and basically truncated by, the sense of their overridingly social constitution.

It seems unlikely that modern socioculture could effect so profound an ontological and phenomenological transformation as to realize such a radically different sense of the individual, a sense in which the self is naively conceived of as primarily other to itself, and individuality is primarily determined by reference to, rather than rationality and moral autonomy, idiosyncratic differences between one individual and another. Given that societies characterized by a non-Cartesian and non-Kantian sense of the individual also exhibit inhuman practices of their own, one might wonder whether such a transformation is even desirable. It might seem, then, that in modern society, with its characteristic feature of intensive self-consciousness, significant change is a matter of raising that consciousness to entertain, sincerely, values that serve to drive home the significantly dehumanizing nature of prevailing practices. How to do this is of course the problem; and when one considers that in point of fact such salutary values are already widely broadcast in modern society, with the incongruous result of reinforcing the very inhumanity these values oppose, the enormity of the problem is brought into relief.

Possibly the desirable phenomenological and ontological change hinges on acts that by their very doing alter the social order and the consciousness of its inhabitants at the very same time. It so happens that a biblical insight provides a prototypical example that luminously captures this remarkable human dynamic. In the myth of Genesis the first man and woman, by 'choosing' (if only in effect, since their self-consciousness at the time of doing so was largely embryonic) to ignore a threateningly lethal commandment (by their maker), virtually create their very own *world* while, concomitantly, realizing their very own *selves*. In other words, through, what is best described as a childlike (the standard exegesis in terms of sin, being based on an anachronism, amounts to tendentious hyperbole) but death defying act, the couple raise their consciousness, becoming acutely aware of their selfhood, which is to say, their moral sovereignty to create their own ends and values. As a consequence of this development, the myth goes on to remind the first couple, emphatically, not to take too seriously their newfound selfhood, for if only because there is no denying death's dominion, the sovereignty won is ultimately illusory.

It would appear that both communalism and collective movements for social justice have the utopist potential to revise and elevate consciousness just so. In the present relevance, these social enterprises may well promote liberation from the naïve way in which, in today's modern world, the rule of self-interest is rationalized as natural and ultimate. In doing so, the enterprises nurture the contemplative understanding of the self as vitally a manifestation of otherness and others. Such a radical turn of consciousness implicitly portrays the Genesis myth as a registry (albeit religious) of an essential human experience, namely, the emergence of intentional reflexivity and moral consciousness from a state of naiveté. In this connection, the particular conversion projected by the kind of collective initiatives in question here entail a reversal of intentionality: the truth of the primacy of relational holism becomes, contrariwise to the biblical myth, a product of conscious enlightenment, whereas the acute self-awareness recorded, in the myth, as an ascension of self-consciousness gets reconfigured as a naïve prejudice, powerful but intrinsically deceptive and, in its rabid individualism, ironically dehumanizing. In effect, the self-awareness gained in the biblical tale becomes, with the turnaround of intentionality, hyper-reflexive, grasping itself as – paradoxically, and in view of the absolutely vital connection of the self to others and otherness – fundamentally limited and dependent.

Standing together with the perception of humankind as inherently social, this ethically and politically felicitous elevation of consciousness cannot be gainsaid. But the selfsame epistemic development – the awareness of self-awareness as given to self-aggrandizement and perfectibilism – recalls the underlying *anthropological* theme of the biblical story: the fact of, in its basic secularity, man's finitude. Hence, for all the relative success of such communal and collective social enterprises, should we not acknowledge and expect, from the perspective of social science, consequential imperfection? That is to say, aren't these enterprises best conceived as promissory events that at no time can conclusively fulfill their promise but only continue to promote it through deliberation, creative practice, and interminable struggle with the inevitable backsliding and impediments?

Given the intensive nature of ethnographic fieldwork, it is not surprising that the anthropological study of communes tends to be distinguished by sharp attention to the discrepancies between communal practice and ideological design. In staying acutely mindful of this question, the anthropologist is dwelling on a theme at least implicit in the very operation of such communities. The ideological presumption of dualistic opposition between the individual and society defines the communal endeavor as dependent on self-sacrifice for its success, thus projecting the endeavor as a trial of transcendence in the face of material adversity. The adversity is typically apprehended as a matter of the pressures exerted by the external social environment. The adversity is also associated, by communards and researchers alike, with a naturalistic presumption of individualism and self-interest. The research interests of socialization, adaptability, internal conflict, women and work roles, familism, crisis management, commitment, etc. revolve round the ideological picture of these communities as social experiments under hostile conditions, and amount implicitly to attempts at measuring the success or failure of the communitarian enterprise.

As informative as the anthropological focus on the gap between theory and practice is, though, it falls short of the unique advantage anthropology has to offer, for it tends to confine the anthropologist to the communal endeavor's ideological social compass. That compass misleads, in part but significantly, by the presentation of itself as alternative or 'other': it is after all an integral function of the social universe against which its alternance is defined. In principle, however, even if working 'at home,' the anthropologist takes his or her direction from a more radical otherness, one that cannot be reduced to what is already known, at least not without disrupting or altering the latter. Thus, Plath's work in Japan may well disclose a communalism that is not dualist in the received (Western) sense of the term, and Evens's on the kibbutz, digging deconstructively beneath the ideology to

a nondualist mythic core, begins to rethink the very idea of the difference between theory and practice, away from its implicit perfectibilism and toward a relativism that serves to reform 'ethics' as the very name of human existence.

Given the radical way in which they tend to predicate a dualism of the individual and society, communal orders constitute exceptionally fertile ground for anthropological study. Because they thus magnify a fact that ordinarily gets taken for granted, their study helps explain, as Durkheim asserted of exceptional ('pathological') social phenomena, the norm. By the same token (the conspicuous disclosure of individual-society dualism), since the relation between the individual and society is also a predicative question for social science inquiry, the study of these societies critically orients self-examination into anthropology's own tacit foundations. In their connection, it is important to bear in mind that the dualism of the individual and society presupposes – as in, for instance, the work of two imposing figures of Western thought, Descartes, and Kant – the Western notion of the autonomous individual. But the annals of traditional anthropology are filled with studies of peoples who do not entertain so radical a conception of individuality. As many ethnographies attest, this gives us no reason to conclude that such peoples already reside in the paradisial gardens imagined by communards. Provocatively, though, it strongly suggests that underlying both the establishment of communes and the problems that beset them – especially the problem of the individual's 'investment' in the social whole – are certain axial ontological preconceptions.

Communication and Transportation, History of

Franz Baltzarek, University of Vienna, Vienna, Austria

Published by Elsevier Ltd.

Abstract

The history of communication refers to a broad and loosely integrated field of historical research, which includes parts of the history of transport, traffic, communication, media, and information techniques. It is a relatively young field and a new point of view within historical science. Some aspects have been partly studied by historians – economic historians in particular – for a long time, especially the role of new technologies in transportation and traffic and the history of the railways, ships, and automobiles, and telephone and telegraph. The history of journalism and newspapers, as well as the history of photography and films, had been studied for a long time. Since the 1970s new questions and combinations have arisen in respect of the revolution in communication (including computation, multimedia, and the Internet) and these have given an impetus to broader research.

The history of communication is a broad and loosely integrated field of research that includes elements of the history of transport, traffic, communication, media, and information techniques. It is a relatively new field and has developed an innovative perspective in historical scholarship. Some aspects of communication history have been partly studied by historians – economic historians in particular – for a long time, especially the role of new technologies in transportation and traffic; the history of the railways, ships, and automobiles; and the development of the telephone and telegraph. But there are also numerous more recent developments, some of which will be dealt with here.

Overlapping Concepts

The term 'communication' was first used in England within the sectors of transport, commerce, and trade immediately before the Industrial Revolution. It was the time of the extension of the road system with turnpike roads, of new attempts at canal building, and of the emendation of the British postal system. The improvement of roads; the regulations governing the use of rivers; the construction of canals; and the improvement of coaches and cars, boats, and river- and ocean-going ships, were aimed at more transport capacity, the reduction of high costs of transportation, and the widening of local and regional markets to national and international parameters. The Industrial Revolution from the 1820s onwards opened up transportation with the construction of railroads and steamships; and communication was improved by the telegraph and telephone.

Today these forms of facilitating the services of commerce, trade, and tourism – including the later inventions of automobiles, progress in the building of roads, and the development of air transport – are described under infrastructure and its technical equipment. There is therefore an overlap between infrastructure and communication and the last term has become more and more subsumed under the name of 'media.' Communication nowadays is only partly concerned with matters of transport and traffic and there is danger of a one-sided contraction of the content of this term, because the media and media devices are only partly subsumed under infrastructure.

Economists, especially those in public finance, normally define communication and transport as a necessary prerequisite for development and growth, calling it 'infrastructure,' (Hirschman, 1958; Tinbergen, 1962; Jochimsen, 1962, 1966). Before the production of goods for a broader market, a well-functioning transport and communication system is essential. The term 'infrastructure' is a word that originally came from French railway idiom and was adopted by NATO after World War II. Later economists used it as a new term. Good 'material infrastructure' includes the communication possibilities of roads, canals, railways, ships, and, of course, all media equipment.

But 'infrastructure' includes not only 'material infrastructure,' it also refers to 'immaterial infrastructure,' or learning, education, schools at different levels, universities, research institutes, etc. The role of communication in the diffusion of knowledge and information is evident. According to Kuznets (1959, 1965, 1966) 'infrastructure' was one of the most important prerequisites for the European Industrial Revolution. It guaranteed stable economic growth, the international and regional division of labor, made an impact on specialization, and ensured better economic, social, and cultural integration.

Today 'communication' is used especially in connection with the media. The rapid development of the media since 1970 culminating in the Internet, necessitated a new classification of all items of media techniques and their former use: from the human voice and messengers to ballad singers or actors in a theater; from writing, handwritten codices, and letters to printing in books, pamphlets, newspapers, and posters or typewriting; from pictures, drawings, and paintings to photos and since the late 1990s scanning possibilities; from messages given through drums, written on stones, papyrus, parchment, and paper to transmission by telephone, telegraph, film, radio and TV, CD-ROM, DVD, the computer, and the Internet. As a result, the discipline of journalism has widened its scope to include all the mass media and even studies their history. More and more sociological and psychological aspects were introduced in defining the different stages of mankind's communication modes. In this context, M.T. Poe (2010) speaks of five stages of development of mankind from a 'homo

loquens' to a 'homo scriptor,' a 'homo lector,' 'homo videns,' and then to a 'homo somnian' (humanity in the age of the Internet).

There is also an overlap with the term 'information,' which is especially stressed in economics and business science as an important outcome of communication and defined as the ability to share information. Since the 1960s 'information' has been seen as the 'new immaterial resource' in physiology, sociology, psychology, pedagogy, linguistics and information science, ethnology, political sciences and law, and, last but not least, in a bundle of technical sciences.

In economics, for example, it was F.A. Hayek (1968) who described markets as spontaneous networks of information about goods and services. In a competitive market, the profits make it possible to have and to use more information than normal and provide information easier, faster, and cheaper. Market prices in normal (competitive) situations provide very precise information about shortages and abundances, qualities, monopolies, and so on. Business scientists study the organization of firms and the optimization of information within business entities and they stress 'information' as an important factor of production.

As Pool (1963) points out, communication is a fundamental necessity for human social action. Therefore we can distinguish between: (1) interpersonal communication = information exchange within an individual person; (2) intrapersonal communication = information exchange between two or more persons; and (3) media-bound communication = exchange of information between media producers and media consumers (in mass consumption). Since the 1980s communication has come to mean not only exchange of information between human beings but also between computers.

The development of communication and transportation possibilities shows, in the very long run, a dramatic widening of the abilities and capacities of human communication. From the stages of primarily personal experience of communication by ears and eyes, it shifted to a secondary system which is technically arranged and represents 'artificial' communication (S. Krämer, 1997). Today this 'artificial' communication has reached a peak in the new media possibilities of TV, the PC, and the Internet. McLuhan (1964) points out that individuals recognize their environment primarily through the media, which increasingly use the new techniques of electronically transmitting and storing information. His diagnosis is that 'the medium is the message.'

According to N. Luhmann (1981) social systems can be defined as the possibilities of human beings (in their time–space related contexts) to take part in the experiences, procedures, and activities of society. Their ability to participate is, however, dependent on the availability of communication and transport equipment and techniques. Religious and political barriers or facilitations; problems of economic and social inequalities; and the concept of 'property rights' play a role.

The historical sciences, i.e., political, social, and economic history, as well as the history of technology, study the causes and consequences of the communication process from antiquity to modern times. As communication and transport are important prerequisites of development and globalization, one has to examine very thoroughly the rise of the West to see how it obtained leadership over the East. To a large extent, this leadership originates from better and new infrastructure and the organization of transportation and the media. Every step of European development since the Middle Ages can be seen to have happened in conjunction with big spurts and crucial points in the improvement of each new media and infrastructural equipment.

The European case also seems to show that with the improvement of media and transportation, a growing displacement of the state and the old elite went hand in hand with the increasing participation of human beings in communication. N. Elias (1939) in his famous book on civilization has pointed out the strict limitations of monopoly power in western societies. This freed the way for more and more social groups and individuals to use communication and transportation techniques – from the *cursus publicus* of the Roman Empire (which was only open for the purposes of the State) to the new postal system at the beginning of Early Modern Times; from the grand tours of the aristocracy and the commercial journeys of single merchants to mass tourism; from illiteracy to dense school systems; from the handwritten codices of the monks to Gutenberg's first printed Bible and Jerry Cotton; from the transport of gold, silver, silk, and amber to the transport of bulk goods over the whole globe; from the limited diffusion of knowledge and messages by fire signals, letters, etc. to the world wide web in the 'global village' with a 'global information infrastructure.'

Phases of Development in Europe

Historians and media specialists think that within western culture one can find four revolutions and periods in communication and transport development: (1) the Middle Ages (especially from eighth to fourteenth century AD); (2) the Early Modern Times (fifteenth–seventeenth century AD); (3) the onset of and then the Industrial Revolution (eighteenth–first half of the nineteenth century AD); and (4) the Communication Revolution, beginning in the last decades of the twentieth century.

M. Weber (1896) in his famous article on the decay of the Roman world sees the communication and transportation deficit in the Roman Empire as the single, main cause of its decline. He argues that all ancient high civilizations from China, Mesopotamia, Egypt, and the Greek world were river- and shore/coastal-oriented civilizations. The failure of the Roman Empire was that it went deeper and deeper into the European continent. Though the quality of Roman road building was very good and a relay system of changing tired for fresh horses enabled people to cover distances as far as 300 km a day, the ancient *cursus publicus* had not enough impact on common trade, commerce, and communication, because it was not open to the common man.

The Middle Ages and the Early Modern Times in Europe found new answers and, in the long run, more stable solutions in communication, and thus prepared the way for the great spurt of European civilization which, from the sixteenth century AD onwards, left behind the older and richer civilizations of Asia. In The Middle Ages (from the tenth and eleventh century AD onwards) the feudalistic system weakened the state and centralized authority, but strengthened local and regional authorities. At this time, dense networks of more or less

autonomous cities were created, in which trade and handicraft were defined as a primary privilege of citizens and new, dynamic dimensions of the concept of property rights' were introduced to the feudal manors. New communication and information techniques and systems were tested. We can see this in regional and interregional trade with new types of merchants and new commercial institutions (such as fairs and marketplaces), trade guilds, commercial law, special organizational forms of storing, borrowing, and changing money – all these were the outcome of perpetual communication. The consequence was a very rapid diffusion of technical knowledge in mining, architecture, handicraft, and agriculture.

This new system was open for inventions from the Orient, the Arabs, and the Islamic world and accepted new insights from China and India. Technical inventions which revolutionized communication and transportation were the horse collar (tenth century, used in China since 450 AD) and the stirrup. From 1200 AD onwards the diffusion of the use of Arab numbers began and made trade much easier. The compass and the compass needle (used in China from 1075 AD onwards), adopted from about 1200 AD, improved navigation. Though the quality of the techniques of Roman road building could not be attained, the opening up of roads to everybody was a big improvement on the *cursus publicus* in the ancient Roman world. In about 1380 AD cities, religious orders, and guilds introduced the new system of sending messages regularly and over long distances through private postal systems.

Predominantly face-to-face communication, using primarily oral means of information, shifted more and more to a written media stage. The monasteries and the first universities with already-formed libraries had a great impact on learning and knowledge. From the middle of the fourteenth century AD onwards, the improvement of shipping on the rivers through the construction of canals and canal locks began. Measuring time took on new dimensions with the invention of more precise clocks with wheels at about 1330 AD. From the mid-fourteenth century AD there were clocks on the towers of churches. In 1510 AD, the first pocket watches appeared.

The Early Modern Times brought about the second revolution of communication in Europe. The adoption of Chinese navigation techniques was completed; the compass freed the way for discoveries and the exploration of the New World. Trade in mass goods began. This became easier when plantations began to produce 'fungible goods' (like tea, coffee, cotton, and tobacco), which enabled a new trade on commodity markets.

The production and the use of paper and the idea of the movable type for printing (Johannes Gutenberg, 1397–1468 – also of Chinese origin; the first printed book appeared in China in the sixth century AD) brought about the shift from a 'written' to a 'printed' culture. Books now could be printed at a relatively low price and in large numbers. The woodcut print (first used in 1400 AD) and the copperplate print (first used in 1446 AD) now could be combined with the new printing technique. Pamphlets were printed and could be easily distributed. Political and religious controversies, teaching, and learning took on new dimensions. Newspapers were introduced. The monopoly on science and information was broken. The book became important for the unlimited storage and diffusion of information. The pamphlet was used for political discourse and opened up possibilities for participation in political and religious debates; and the newspapers opened the way to inform a growing number of readers about recent events in society.

The sovereigns of territories reorganized their postal system and widened communication possibilities – for example, in 1486 AD the 'Kurfürstliche Botenanstalt' was introduced in Brandenburg. In 1490 AD the postal system in the German Reich was reorganized under Maximilian I. In 1516 AD the Vienna–Brussels postline was introduced, while the Brussels–Rome postline was introduced in 1522 AD by Thurn and Taxis of Vienna-Nurenberg. The new communication advantage cleared the way for an European expansion over the Atlantic and created a second West in the New World of America.

The third revolution began before the Industrial Revolution and influenced the period up to the present day in three stages. In the first stage, the mercantile system introduced more regular traffic, a regular postal system, and supported canal- and road-building. Milestones in France included the 'Canal du Center' between the Loire and the Saône (1555 AD) and the 'Canal du Midi' between Southern France and the Atlantic (1666–81 AD). Soon after, many canals in German territories, in the Dutch Lands, and in England were built. The introduction of railways from the 1820s and 1830s onwards, the intensive use of steamships from the 1850s and 1860s onwards, the common use of telegraph, telephone, and the overseas cable since the 1850s to 1870s, (and especially the spectacular opening of the Suez and the Panama Canals) marked the second step, which reached its peak in a highly integrated global world economy before World War I.

The automobile and new road-building – especially in the form of highways – and the victory of the street over the railway and the airplane, widened communication and transportation possibilities in the following interwar period. This brought greater reductions in the regional differences in prices, greater allocations of production and resources, more division of labor, mass production for wide national and foreign markets, standardization, and the unification of languages, morals, and tastes. The third step began in about 1970 with the 'post-industrial phase' or the 'age of information.' The multimedia revolution brought the technical inventions of ISDN, the mobile phone (cellular phone), the fax, the PC, and the Internet (www, online and e-mail), and digital forms of TV, broadcasting, and printing – the 'information superhighway'.

The economic consequences were e-commerce, telebanking, more foreign investment in many countries, and a very sharp decrease in the costs for information and transport, globalization, digital traffic engineering, and teleworking. The socio-cultural consequences were teleteaching, a networked scientific community, and telemedicine. The political consequences were e-government and smart cards for electronic administration systems.

Historiographical Trends, Further Research, and New Fields

The historiography of former times seldom studied communication and transportation. Since the turn of the nineteenth century, 'economic history' achieved an independent status and transportation problems were described under the aspect of commerce. In the period before World War I in nearly all

industrialized countries, the first technical museums were created. They had a great impact on the study of the history of technology and innovations, especially railways, cars, automobiles, ships, airplanes, and information devices like the telephone and telegraph. The history of technology became a new subdiscipline within economic history. In the last few decades, the science of journalism has widened to a science of media and examines all media, especially mass media, in the historical context. Today a modern history of communication has to combine all these fields in cooperation with other social and economic disciplines.

This broad approach is also represented by the International Communication Association (ICA). Its forerunners go back to 1950; since 2003, ICA is officially associated with the United Nations as an international nongovernmental association. ICA also has a section studying communication history.

There are, of course, many possibilities for further historical research in the field, e.g., studies on the regional, national, and worldwide diffusion of communication and transportation techniques; crowding out and/or supplementary processes between the different communication technologies; the social consequences of media revolutions; the impact of the media and the transport revolution on political situations and military conflicts; the access to communication and information techniques; religious and political control and inhibition of communication (censorship); the effects of the transport revolution within economic development; the role of official and nonofficial statistics in information about economies; and the consequences of changing communication and transportation in mass tourism, leisure, and hobbies. Other possibilities include the rise of special cultural forms, traditions, and customs concerning, for example, letter writing, traveling by coach, railroad, automobile, ship, and airplane, and studies of the intensification of communication in personally written as well as in digital communication.

Even completely new fields can be developed under the aegis of communication. One example may be the creation of European 'financial intermediation' in banking and in stock exchanges. It developed as an important new way of communication in the economic and business sphere of the seventeenth and eighteenth centuries.

How to finance firms and enterprises and how to finance states and their budgets – these are the important questions in every modern economy. In former times people who had large savings and lent to the state or to private entrepreneurs could not get back the money before the end of the agreed term. So, normally, the only possibility was to hold large stockpiles of money, without being able to lend it, in order to remain liquid at any one time. This problem was shared by wealthy individuals and institutions, such as insurance companies, managements of orphans' properties, etc. No civilization had managed these problems adequately until Europe found new ways of communication to bring together lenders and borrowers. There are four areas that highlight this information and communication revolution in banking since the seventeenth century AD.

1. Since the period between the fifteenth and seventeenth centuries AD, communication and information has improved through investment in new roads, cars, ships, canals, and new media techniques. The unification and standardization of goods also brought improvement, especially through the creation of 'fungible' goods, wherein one item stands as guarantee of quality for all the other pieces of this product. Markets could thus be transformed partly into markets with 'fungible' goods. The exchange in products for certain metals and for certain crops, especially tropical plantation crops like cotton, tea, coffee, sugar, etc., was born. This facilitated economic communication enormously. As the qualities of these goods were defined *ex ante* and were well known, merchants could deal in great volumes of these goods and articles without actually bringing them physically to the markets. Transaction costs were thus dramatically reduced.
2. In combination with stock exchanges the experiences with 'fungible' goods were transferred in the seventeenth century to the financial sector. The creation of fungible bonds for the state and public authorities (instead of individual obligations for single lenders in former times, which could not easily be transferred to other capitalists) pulled hidden private stockpiles of wealth into the public economy and brought the money into the hands of sovereigns and governments. This idea spread to fungible shares for enterprises. Now it became possible to erect big enterprises in the form of joint stock companies. The first joint stock companies were firms within the trading sector, followed by companies in infrastructure and communication; by companies in the banking system; and last of all by big industrial firms.
3. The next point in this development was the improvement of the financial mediation of banks. A new type of bank developed, which brought together people who had money but did not need it at the time and people who did not have enough money to make productive investments in business. The 'goldsmith bankers' of London were the first to succeed at this business, because they found out that the communicative role of a bank has to be the transformation of risk, of terms, and of size. Fungibility and the new communicative role of banks became the main facilitators for a 'financial revolution,' which was a precondition of the financing of the Industrial Revolution.
4. Since the beginning of the twenty-first century new steps in financial communication have been taken, especially in the context of the PC and Internet systems. New generations of financial products have arisen, including e-banking and new techniques of worldwide speculations (high-frequency trading).

Abstract

Communication research is both the latecomer of the social sciences and a product of political and economic necessities. The discipline's formation took the search for effective propaganda designs and a growing interest of both media industry and students. Furthermore, the field's development is inseparably linked to the history of US universities. First, the strong emphasis on quantitative research was invented precisely there. Second, communication research made in the US was exported worldwide.

Communication research is both the latecomer of the social sciences and a product of political and economic interests. In the first half of the twentieth century, other social science disciplines like sociology, economics, anthropology, psychology, and political science were born but not communication (Abbott, 2002). The discipline's formation took World War II with its interdisciplinary work on propaganda that was clearly conditioned by Rockefeller Foundation's support, military, CIA, and State Department funding (Pooley, 2008) and the search for effective propaganda designs in the early Cold War sponsored by the very same agents (Simpson, 1994; Glander, 2000). Last but not least, it was a growing interest of both media industry and students that "communication research began to be recognized as a distinct academic field" (Craig, 2008) or, as in the case of German *Publizistikwissenschaft*, solved its legitimacy crises by a shift from a humanistic to an empirical social science pleading for the use of quantitative methods (Löblich, 2007). However, Robert Craig (2008) associated the 'rapid growth and institutional consolidation as an academic discipline' that communication underwent since then with certain problems: strain on resources, an overemphasis on practical training of undergraduates, and the threat of cooptation by commercial interests. To put it in a nutshell, in terms of scientific capital, the latecomer communication research seems to be still at the bottom of the table rather than at the top.

As the article's title already suggests, both the field's name and status are contested. All over the world, communication research and media studies are torn between social sciences and humanities and highly diverse in methods, theories, and objects of study (Craig, 2008; Averbeck, 2008). Not even in the US, the field has a singular authoritative institution like the Modern Language Association or the American Anthropological Association. In addition to purely academic associations such as the International Communication Association (ICA, more than 4000 members in over 80 countries) and the International Association for Media and Communication Research (IAMCR, 1500 members from some 100 countries), there are both associations that also embrace educators, teachers, politicians, and practitioners (National Communication Association, Association for Education in Journalism and Mass Communication, World Association for Public Opinion Research) and those that focus on very specific topics in cross-disciplinary fields (Society for Cinema and Media Studies, Association of Internet Researchers). Furthermore, even some of the field's most prominent figures such as Byron Reeves (2012) from Stanford view communication 'very much as a subject and not as a discipline like psychology or biology' to this very day. For all these reasons, the question continues to be key today whether communication research and media studies is already (or still) a discipline rather than 'one of the great crossroads where many pass but few tarry' – as Wilbur Schramm (1959) puts it against Bernard Berelson's death pronouncement in the *Public Opinion Quarterly* debate some 50 years ago when this academic enterprise was just new born (Wahl-Jorgensen, 2004). Part of the field's legitimation and identity problem are the notions of an 'academic Taiwan' (claiming all of China as its own, Peters, 1986), or, similarly unfavorable, of a stepchild that is tolerated by university administrators only because communication research and media studies helps pay the bill for the departments they really care about (Meyen, 2012).

The Field's Historiography

From the early days on, the history and present day structures of communication research and media studies have been of particular interest to those who are within this field (Dennis and Wartella, 1996); in part as a tool for 'authentication and legitimation,' easy to understand against the just outlined background, and partially because there seems to be neither significance nor identity without historiography (Hardt, 2008). The rich and growing body of literature on the field's origins has a certain focus on the intellectual roots of the discipline (Peters, 1986, 1999; Rogers, 1994; Hardt, 2001; Park and Pooley, 2008). There are 'milestones' (Lowery and DeFleur, 1983), edited collections of key or canonic texts (Katz et al., 2003; Peters and Simonson, 2004), myths told over and over again about both the four founding fathers Carl Hovland (1912–61, a psychologist), Harold D. Lasswell (1902–78, a political scientist), Paul F. Lazarsfeld (1901–76, a sociologist), and Kurt Lewin (1890–1947, a psychologist again) and the institution builder Wilbur Schramm (1907–87) who started the programs and institutes at Iowa in 1943, Illinois in 1947, and at Stanford in 1955 (Rogers, 1994; Chaffee and Rogers, 1997). On the one hand, those biographical approaches have been criticized as 'great-men-make-history' tales (Löblich and Scheu, 2011; Simonson, 2008) but on the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03054-3

other hand, there are portrays of the most promising female communication scholars based on personal conversations (Signorielli, 1996) or archival work (Dorsten, 2012) as well as current interviews with 57 leading scholars (Meyen, 2012).

Looking at the importance of propaganda back then, it seems easy to name the 'wartime research effort' as "the single most important catalyst for the new field of communication research" (Wahl-Jorgensen, 2004) and to point both to the need for legitimization and to the scholars coming in from various disciplines to study public opinion, mass media effects and persuasion (Glander, 2000; Simpson, 1994). However, there are also sophisticated trials to locate the discipline's development and institutionalization within "the context of communication as an evolving category of cultural knowledge and practice in society" (Craig and Carlone, 1998; Craig, 1999) or 'within the system of American higher education' (Delia, 1987) and academic structures (Pooley and Katz, 2008). Besides those dominant narratives, there are alternative constructions of the research field's history available (Carey, 1992; Hardt, 1992). The very same is true for research on almost all the facets of an academic hierarchy – on the relative positions of the different areas in relation to others in the field (Donsbach, 2006), on masters and doctoral programs (Craig and Carlone, 1998; Barnett et al., 2010), on 'the most important theorists' (Beniger, 1990), on citation patterns (Park and Leydesdorff, 2009), on research productivity both of individual scholars and departments (Bunz, 2005), and on leading associations (Weaver, 1977; Nordenstreng, 2008).

The Field's Geography

The academic discipline of communication research is (still) a US centered enterprise with strong pillars at the Big 10 universities and the West coast. There are no communication research and media studies programs at most Ivy League schools and other top-tier US universities. Stanford and the two Annenberg Schools for Communication at the University of Pennsylvania and at the University of Southern California (USC) in Los Angeles are three exceptions to the rule that the field's heart beats not at private US schools but at the large public research universities such as Illinois, Indiana, Iowa, Michigan State, Ohio State, Penn State, Purdue, Texas, and Wisconsin. Contrastingly, 'the golden era at Stanford' seems to be over. According to eyewitness Everett Rogers (1994), it is not so long ago ('from roughly 1955 to 1970') when that university 'dominated the field' and everybody would have wanted to hire one of Stanford's PhDs in communication. From that period is not too much left. Today, Stanford only has a rather tiny number of people in human–computer interaction and mass media studies (Reeves, 2012).

The dominant historical narrative that explains the field's geography is, at least in this case, quite similar both in the journalism- and speech-derived traditions (Rogers, 1994; Cohen, 1994; Pooley, 2008). Looking at those histories, the development of the communication research field is inseparably linked to the history of US universities. The land-grant schools were established to help develop the new territories of the US. In these universities, practical skills such as speech, rhetoric, and journalism were more respected. The focus on practical activities and the idea of instrumental tasking attracted a certain type of students: kids of social climbers and, in particular, of European immigrants. Conversely, the US elite universities repositioned themselves along the lines of science in the early 1900s (Meyen, 2012).

This narrative fits into Klaus Krippendorff's construction of communication's early days at the University of Pennsylvania in Philadelphia. Krippendorff (2012) who became an assistant professor in 1964 at Penn: "Walter Annenberg was the owner of *The Philadelphia Inquirer* and wanted to pay for a school that would create professionals that could work in his newspaper. The University of Pennsylvania didn't want to have a narrow professional focus but liked the idea of a communication school." Consequentially, the Annenberg School focused almost exclusively on research. The strong position of the Annenberg Schools at Penn and USC within the communication research field is not just a heritage of the long-term dean George Gerbner (1919–2005, in charge from 1964 to 1989) or a function of the commercial context the two are settled in. "One of our strength was financial," said Klaus Krippendorff (2012). "Walter Annenberg provided ample resources."

In the case of Stanford, it is more about reputation than just dollars. Everett Rogers (1994) first listed the eight US schools with the highest prestige (they 'tend to be private, old, and resistant to radical educational innovations') and then celebrated, logically from his point of view, "Schramm's move to Stanford University in 1955 and the founding of the doctoral program there" as "the key event in gaining acceptance of communication study in American universities." However, more than half a century later, Byron Reeves (2012), Schramm's successor's successor, still has to fight for the reputation of the discipline: "Everybody is always asking what communication is and why they don't have it at Harvard, Princeton, Yale, or most of the other top ten or top 20 universities. That's where the peers for all the other departments are." Therefore, both the geography of the field and its roots in more practical skills such as journalism and speech have implications for communication's position in the larger scientific field.

Concentrating on communication research and media studies' beginnings in the US does not in any way mean a devaluation of other world regions. Of course, there are similar developments in Europe in the first third of the twentieth century. It is well known that Paul F. Lazarsfeld who became an important point of reference for US centered historiographies of the communication research field started out in Austria where he, to give just one example, collected data on the listening habits of radio audiences in the early 1930s (Fleck, 2007). In Germany, the *Zeitungswissenschaft* (newspaper science) was established at universities during World War I in order to raise the level of journalism in the fight for public opinion (Löblich, 2007). However, it is not just the common root in practical training and administrative research that legitimizes a certain focus on the United States. First, the strong emphasis on quantitative research, including statistical methods and sophisticated data analysis, that became one of communication research's key identity elements from the late 1950s on and will be described in the next paragraph, was invented precisely there. Second, closely linked to the shift from training offerings to academic

approaches, communication research made in the US was exported worldwide. To put it another way, many of the founding mothers or fathers of national scientific communities were not just heavily influenced by the North American research tradition but rather a part of it. The exceptions include France and southern Europe where it was not until the 1970s that the discipline began to spread, Eastern Europe with its roots in Marxist–Leninist traditions of journalism training, British Cultural Studies and parts of Latin America (Averbeck-Lietz, 2013).

It is easy to see that the dominance of US-originated approaches to communication research and media studies is a function of both the power of English as the global language and, probably even more important, the level of commercialization of media systems. Media markets create the needs for application knowledge, well-trained students, and a public debate on the individual and societal consequences of commercial media products. That is why it is no accident that US universities not just exported theories and methods but also scholars that became leading figures in other national academic environments. To start with English-speaking countries, the native American Jay Blumler (United Kingdom) graduated from Antioch College. Later, in addition to his position at Leeds where he became one of the most prominent researchers in the field of political communication, Blumler was professor at the University of Maryland. Elihu Katz (Israel) was born in New York, Akiba Cohen (a second Israeli) in Detroit, Cindy Gallois (Australia) in Washington, and Janet Bavelas (Canada) in Portland, Oregon. James Taylor who inspired the famous Montreal School of organizational communication research worked as a lecturer at the Annenberg School in Philadelphia in the 1960s. All five of them got their PhDs at communication or, in Katz' case, sociology schools in the US. Youichi Ito (Japan) who is renowned for his information society concept did a master's degree at Boston University and had a fellowship at Tufts University in the 1970s. Osmo Wiio (Finland) attended an American seminar in Salzburg, Austria in the late 1950s. From then on, Wiio developed strong contacts with the US universities. The very same is true for Kaarle Nordenstreng, the second famous Finn in the international community. In the late 1960s, Nordenstreng had a fellowship at Southern Illinois University mainly working for his doctorate. He got to know communication research by traveling the US and interviewing American colleagues (Nordenstreng, 1968). Elisabeth Noelle-Neumann (Germany), to give one last example, received a scholarship at Missouri's School of Journalism in 1937–38 and was a visiting professor at the University of Chicago on a regular basis between 1978 and 1991. One of her students is Wolfgang Donsbach, who served as a World Association for Public Opinion Research (WAPOR) president in 1995–96 and as an ICA president in 2004–05 and edited Wiley's 12 volumes *International Encyclopedia of Communication* (Donsbach, 2008).

The Shift from a Humanistic and Practical to an Empirical Social Scientific Discipline

Communication research and media studies literally began with the invention of the printed press. However, in the first two and a half centuries after the world's first newspaper appeared in the City of Strasburg (1605, German language), the field remained a sphere dominated by outsiders. In the German language area, novelists, theologians, editors in chief, other journalists, or private scholars wrote about the topic. Although the first doctoral thesis on newspaper reports has already been submitted in 1690 (at the University of Leipzig), although there were a number of lectures devoted to the organization and the usage of the press in the eighteenth century, and although historians, economists, legal and literary scholars started to explore press-related problems with the unfolding of the mass press in the second half of the nineteenth century, German universities were not interested in the foundation of an independent communication discipline until World War I. At this early stage, the impetus for founding the *Zeitungswissenschaft* (newspaper science) came from publishers' and journalists' associations (Meyen and Löblich, 2006).

The German foundation history is an epitome for the field's emergence. In all countries, first, media distribution and academic communication research are closely connected. Second, media innovations had and have wide implications for researching and theory-building in the field of public communication. And third, the demand for qualified journalists, PR specialists and, at least in the US case, debaters was a major driving force of the field's academic institutionalization. In Germany, both *Zeitungswissenschaft's* forefathers and founders started out in journalism. They mainly focused on journalism education as well as on the discipline's legitimation and, therefore, could not improve their status at university. Furthermore, National Socialism stopped initial steps toward theorizing communication and media phenomena by forcing promising Jewish scholars into exile (Averbeck, 2001; Fleck, 2007). Those German researchers who could carry on in that period were compromised after 1945. The discipline's reestablishment was, again, the work of trained journalists such as Walter Hagemann (1900–64) who coined the term *Publizistikwissenschaft* and reinvented communication research and media studies from scratch (Wiedemann et al., 2012). Although Hagemann already experimented with social scientific methods, German *Publizistikwissenschaft* was still dominated by humanistic and practical approaches.

However, all over the world, well-rounded communication-related doctoral programs were not established until after World War II. Whether implemented in former journalism schools or speech departments, the new born US graduate programs emphasized quantitative empirical work. Rogers (1994) described the not just epistemological conflict between the nonscientific 'Green-Eyeshades' ("oriented to the profession of journalism rather than to the new science of communication") and the 'Chi-Squares' who survived in the end because their scholarly approach fit with the norms of research universities. In addition to the media industry that became engaged in polling and market research (Rogers, 1994; Löblich, 2007), the students experienced a kind of epiphany that matched the habitus of social climbers who focused on the idea of contributing socially. At least in the 1950s and 1960s, young journalists as well as young debaters went out into

the world to make a difference. Involved into scientific research projects, the future communication research professors became convinced that the answers derived from Hollerith machines and supported by statistical techniques would influence journalists and others (Meyen, 2012).

Michigan State University played a special role in the shift from a humanistic and practical to an empirical social scientific discipline. That shift is especially linked to the name of David Berlo (1929–96) who was one of the first individuals to receive a PhD degree in the new field of communication (at Illinois). Berlo founded the department at Michigan State and continued as chair for the first 14 years (1957–71), starting out not even 30 years old. According to Everett Rogers (2001), Berlo saw "that training large numbers of doctoral students was the route to implementing a social science conception of communication." To Gordon Whiting having a speech and rhetoric training, Berlo would say, "we are making a scientist out of you." Berlo's closest allies Gerald Miller (Iowa), Hideya Kumata, and Erwin Bettinghaus (both Illinois) had been trained at schools founded by Wilbur Schramm too. For Rogers, who came 'from an established department at Ohio State (in sociology),' at Michigan State the 'the close-knit nature of faculty relationships' was kind of new. That as well as the quantitative orientation he traced back to "the high degree of uncertainty about the new field of communication study" later. As chair, Berlo would perceive that his department was at risk and "convince his faculty to pull together against a hostile environment." In Roger's memoir, there is also a brief glance at Berlo's habitus: a bodyweight of over 270 pounds, hidden in 'well-tailored dark suits' and so pretending establishment (Rogers, 2001).

There could be no doubt that the Michigan State habitus began to rule the field very quickly. Parts of it were the strong emphasis on quantitative research, including statistical methods and sophisticated data analysis, the 'high degree of male bonding,' the notion that communication research is an academic underdog and the feeling that the resultant methodological orientation was superior to any other approaches. That habitus promised "a defence against the possible suspicion by higher levels of academic review that communication was not rigorous enough" as well as personal security for the newcomers at university and is around to this very day (Meyen, 2012).

However, the path to more recognition mapped along the lines set by the natural sciences at the power pole of the academic field has been challenged again and again, too. In addition to the already mentioned British Cultural Studies with its emphasis on power, media content, and media usage, there are other supporters of qualitative methods as well as theoreticians available. For example, Hanno Hardt (2001) called for a paradigm shift to critical communication research. In lamenting the crisis of US-based quantitative approaches, Hardt pointed to the European tradition in analysing the relationship between mass media and society and edited communication-related works of famous German sociologists and economists such as Karl Marx, Max Weber, Karl Knies, Albert Schäffle, and Ferdinand Tönnies as well as early American trials by Albion W. Small, Edward A. Ross, and William G. Sumner.

Communication Research and Media Studies on the East–West Battlefield

It is not just the field's roots in propaganda research during World War II and the postwar era up to the 1960s that stand for the considerable political influence on research problems, theories, methods, and even appointments. A glance at communication's two leading international academic associations today shows how long the road to more autonomy took. Until the mid-1970s, ICA had members from government, from business, and from teachers who did not want to do scholarship (Meyen, 2012).

Unlike ICA, IAMCR could not really extract itself from the grip of politicians or practitioners. IAMCR is a child of the postwar area. Founded with UNESCO support in 1957 'on ecumenical soil crossing both East-West and North-South divides' and in its beginnings dominated 'by Europeans, particularly the French' (Nordenstreng, 2008), those origins dominated the association at least till Cold War's end. From the mid-1960s until the fall of the Berlin Wall the association's conferences were not just about academic results but also (and maybe even more) ideological battlefields. The East European countries tried to influence both the program including the respective publications as well as the recruitment of leadership positions. In essence, three objectives can be distinguished. First of all, the communists wanted to promote their very own concept of scientific work on journalism and mass media effects. This concept included formulas, precepts, and doctrines of Marxism–Leninism. Second, closely linked to the first aim, the East Europeans wished to win colleagues from the developing countries in Asia, Africa, and Latin America for the socialist idea on how to educate journalists and other mass media practitioners. This objective is part of the two systems' worldwide struggle for supremacy back then. And third, along with professors and doctoral students from the third world, so-called progressive Western academics, were also an important target group. Scientists working with materialist or other classic left theories and ideas should be encouraged and helped to present the results of their work to an international audience. Therefore, it was more than a battle of ideologies. Focusing on clearly academic issues such as theory and methodology, the definition of 'good science' was at stake (Meyen, 2013).

Driving force of all those efforts was the German Democratic Republic (GDR). For the communists in East Berlin, international organizations such as IAMCR were a tool in their fight for international recognition. Therefore, they helped to kick-start IAMCR. Formerly known as a rather small association with a permanent lack of money, IAMCR had a major conference in Leipzig in 1974 with about 250 participants from all over the world and two-volume proceedings. Emil Dusiska (1914–2002), leading professor in the communist journalism training center at the University of Leipzig, became IAMCR's secretary-general and did most of the association's paper work from 1972 to 1978. In return, IAMCR's policy was discussed in the communist party's inner circle in East Berlin.

East Berlin communists' support for IAMCR and their advertising for the well-equipped journalism department in Leipzig perfectly match communication research's general situation. Looking back to the late 1960s and early 1970s, we find a small discipline fighting for its existence. ICA 'was more like a family

affair' back then. Klaus Krippendorff (2012) describing the association in its beginnings: "The scholars who gathered at annual conventions knew each other, and the program was printed on one page folded three ways. For me, one of the most interesting conferences was in Phoenix, Arizona, in 1971. ICA rented a motel with rooms around a swimming pool, and there were few parallel sessions. The climate was completely different."

However, beginning in the early 1970s, in the field of communication research and media studies, the academic logic began to triumph over the political one. Apart from GDR's declining interest in IAMCR after joining the UN in 1973 that is the second significant reason of the decreasing influence of Eastern European representatives on the association's agenda. In 1974, Western scholars rejected a plan to launch an official IAMCR journal supported by Eastern European money with academic arguments. In the very same year, interesting enough, George Gerbner reinvented the *Journal of Communication*, which was originally set up in 1951. Within a short period of time that ICA publication became the field's flagship journal.

Summary and Current Situation

The field of communication research and media studies does not have the same aura like established disciplines such as history, literary studies, linguistics, psychology, or sociology. It is comparatively young, rather small and at the same time very broad. Moreover, at many places it is still easy to think of communication as primarily a technical, skills- or service-oriented discipline, not a social science. Citation patterns are an indicator for the field's position at large. More established subjects do not do a good job in searching literature from communication research. A typical political scientist might study the impact of the Internet for political processes, without ever reading a communication journal (Meyen, 2012). In contrast to Sisyphus, there is hope for the field. All over the world, communication has been growing vastly. There is a tremendous demand for undergraduate places. As a result, the discipline gets the best students and therefore, probably the best future faculty on the market. There is a second market force working for communication: a fast growing societal interest in media and communication issues and, linked with that interest, growing outside funding. The access to external money is changing the field right now and is going to shape its future structures, too. A prime example of the ongoing changes is the rise of health communication, but there are other winners as well – organizational communication, new media, and research on children and media.

Communication Skills in Social Work

Barbara Staniforth, School of Counselling, Human Services and Social Work, Faculty of Education, The University of Auckland, Auckland, New Zealand

Abstract

The ability to communicate well with people forms the basis of all social work practice. Being aware of how different cultures communicate is essential in an increasingly global practice environment. Self-awareness is also critical so that social workers can be aware of how they and others filter incoming messages and make meaning. There are certain microskills that form part of a social worker's communication repertoire. These include attending and responding, reflecting thoughts and feelings, asking questions, summarizing and using silence. Social workers need to consider the specific contexts that communication skills occur within and equip themselves for all situations.

Introduction

Good communication skills form the basis of all social work practice. Without them, workers would be unable to form relationships, effect change, or support, advocate, or problem solve. Unlike certain skills that may be fairly straightforward to acquire, such as knot tying or typing, learning how to communicate well is a complex process where learning must occur on several levels simultaneously. Communication in itself is also a process whereby the social worker is only a part of the equation. This article looks at some of the critical issues that social workers need to consider in communicating well with others. It moves from broader areas such as culture and self-awareness to looking at particular skills that are commonly taught to beginning social work students.

Culture and Communication

From the time of conception, people begin their learning about communication. Families form the crucibles where people learn about how to communicate to get their needs met, about emotions, and also about the rules that help people make sense of the world. Families sit within particular cultural contexts that have formed over time. These contexts hold many of the stated, and often unstated, messages that teach people how to communicate 'acceptably' within their cultures. It is important for social workers to recognize not only the messages that they have been given within their own cultures about how to communicate, but also the messages that are inherent in other cultures.

There are various traits within cultures that are important to be aware of when considering communication. Some of these are the degree to which a culture values collectivism over individualism, the degree to which context plays a part in communication, the structure within a culture in terms of how power is recognized, and the degree to which uncertainty within communication is tolerated (Tubbs, 2010).

Collectivism

One of the central differences between cultures is the degree to which they value individual rights and freedoms over the greater good of the group as a whole. Countries such as the United States have evolved with strong messages about individual rights and freedoms being paramount. This is espoused in things such as the right to 'free' speech and the right for people to bear arms. In such situations, people are encouraged to express their own beliefs and feelings about things and to own them as their own. In other areas, such as Japan, China, many Pacific Island cultures, and other non-European cultures, the concept of 'self' is, at times, nonexistent, with each person existing only within the interconnectedness of their families or other cultural groupings. In such situations, people's identities are located within the greater group, and speaking for 'oneself' and having one's own opinions, thoughts, and feelings is downplayed or seen as undesirable. These differences have big implications for those whom social workers see as their 'clients.' Should they communicate initially with the individual or with the whole group? How should that communication occur? For instance, in Māori (indigenous people of Aotearoa New Zealand) culture, it would not be uncommon in a job interview or therapeutic assessment for the individuals themselves not to say very much but to have the family attend and speak on their behalf (Mead, 2003).

Power Distance

Related to the individualist/collectivist variable is how power and equality are seen within cultures. This is known as 'power distance.' Some cultures, such as Korean, Japanese, and many other cultures, value the knowledge and experience gained through age and apportion a strong sense of respect and differentiation in roles between the old and the young. Other factors such as gender may also play a role, with either men or women being assigned certain roles as spokespeople for the group (Tubbs, 2010). These factors are important to consider when thinking about how to make contact and build rapport with clients and their families.

High- and Low-Context Communication

The directness with which messages are given is one of the areas where communication can differ markedly between cultures. Some cultures (many Western ones) believe in the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28119-1

importance of stating things directly, while others believe that getting one's message across more indirectly is more appropriate. These differences are known as 'high'-context and 'low'-context situations, where direct communication (saying exactly what you mean) requires less reliance on the context to send and receive messages. 'High'-context cultures rely heavily on things such as tone and body language to send and receive messages, and may place less emphasis on the words being said (Tubbs, 2010). Listening and paying close attention to the situation is required and it can be difficult for people who have not grown up or lived within the culture to pick up the cues easily.

Uncertainty Avoidance

Related to directedness is the degree to which cultures are able to tolerate uncertainty in their communication. High-context cultures are often able to tolerate a higher degree of uncertainty, as much of what is being said may rest on subtle nuances. Low-context cultures, which are used to speaking and responding in a direct manner, may do so as they have a lower tolerance for uncertainty or ambiguity in communication (Tubbs, 2010).

The above cultural variables have at times been researched and numeric values have been attached to the degrees to which these variables have been demonstrated. These are known as 'cultural taxonomies.' Hofstede (2001) was one of the first sociologists to study and record such cultural traits. **Table 1** demonstrates some of the traits explored through another ongoing study from the Global Leadership and Organizational Effectiveness Research Program, which has explored the relationships between social culture, organizational culture, and leadership traits (House et al., 2004; Smith, 2006). While at times these taxonomies may be useful for bringing awareness of what different cultures value in communication, caution is advised as these taxonomies assume that a nation is composed of an amorphous culture, with subcultures not being taken into account. Assumptions should not be made about people solely based on these taxonomies.

While consideration of the differences in cultural communication styles is important, it is just one of the factors that need to be considered. An awareness of self is also an important skill for all social workers to possess.

Communication can be defined as a process whereby one person 'codes' a message in oral language or other cues and sends it to another person or people. This message is then filtered by the receiver(s), decoded, and then considered. A response then may occur, whereby the process is reversed, with the recipient becoming the sender, coding their message, and sending it back (see **Figure 1**). A critical variable in this step is the 'filtering' process, where culture may play a big role. Another variable at work in the filtering process is worker identity. Self-awareness is important in order to be able to consider how one's history and the multifaceted formation of one's identity contribute to how information is interpreted. In social work, some of this gets framed as transference and counter transference in interpersonal relationships, but it goes far deeper than this (Chang et al., 2009).

Identity and Self-Awareness

Many theories on development frame early childhood experiences as determining how views of self, 'other,' and the world are constructed. Attachment theory describes these as internal working models, cognitive behavioral theory frames them as core beliefs, and psychodynamic theories may consider these to be a person's 'object relations.' Whatever the theoretical orientation, the message being given is that the filters used to interpret information are likely to have been formed in a person's early years and then to have been further reinforced (or at times altered) by subsequent experiences. The quotation from Tennyson's poem *Ulysses*, 'I am part of all that I have met'

Table 1 GLOBE cultural taxonomy

The Global Leadership and Organizational Effectiveness Project (Project GLOBE) (House, R.J., Hanges, P.J., Javiden, M., Dorfman, P.W., Gupta, V. (Eds.), 2004. Culture, Leadership, and Organizations: The GLOBE Study of 62 Societies. Sage Publications, Thousand Oaks, CA.) explored national cultures of 61 nations, focusing on nine cultural dimensions. Questionnaires were used to collect data from middle managers in various industries around the globe over a 10-year period. The dimensions were measured on a continuum. Within the above chart a high positive score indicates that the country demonstrated a high degree of that trait, while a high negative score indicates a low demonstration. Zero is the average score. A brief summary of each trait is found below.
Power distance – the extent to which a community accepts and endorses authority, power differences, and status privileges.
Uncertainty avoidance – the extent to which a society, organization, or group relies on social norms, rules, and procedures to alleviate the unpredictability of future events.
In-group collectivism – the degree to which individuals express pride, loyalty, and cohesiveness in their organizations or families.
Institutional collectivism – the degree to which practices encourage and reward collective distribution of resources and collective action.
Assertiveness – the degree to which individuals are assertive, confrontational, and aggressive in their relationships with others (House, R.J., Hanges, P.J., Javiden, M., Dorfman, P.W., Gupta, V. (Eds.), 2004. Culture, Leadership, and Organizations: The GLOBE Study of 62 Societies. Sage Publications, Thousand Oaks, CA, p. 30).
For further descriptions and critiques of the study see McCrae, R.R., Terracciano, A., Realo, A., Jüri, A., 2008. Interpreting GLOBE societal practices scales. Journal of Cross-Cultural Psychology 39, 805–810. doi:10.1177/0022022108323806 and Smith, P.B., 2006. When elephants fight, the grass gets trampled: the GLOBE and Hofstede projects. Journal of International Business Studies 37, 915–921.

Figure 1 Process of communication.

(Tennyson, 1985: p. 57), demonstrates this well. It is therefore important for communicators to have a good knowledge of their experiences and how they have informed their filters as these are likely to inform how they both code and send messages, and also how they receive others' messages.

Some of the common areas that have been identified in the literature as impacting upon these communication filters are the following:

- the families that people have grown up within, and the rules they have imparted;
- the roles that people have played within their families;
- religious or spiritual experiences;
- the multiple cultures that people have been associated with;
- the connectedness or lack of connectedness that have been experienced with others;
- people's experiences of having their needs met or being responded to;
- gender;
- ethnicity;
- sexual orientation and experiences;
- experiences of safety, trauma, or abuse;
- experiences of being in a majority or minority culture;
- experiences of acceptance or oppression;
- genetic or physiological dispositions;
- experiences of health and illness; and
- the messages that have been given about equality and rights.

The list of factors is endless. Beginning social work students are often given assessments that encourage them to think about how some of these factors have impacted upon them and how they see themselves and the world. They are encouraged to consider how these things impact upon how they code and receive information and how all these same factors may have influenced how others code and receive information. Having this awareness enables students and social workers to see how people are all constructed differently and helps avoid hegemony or cultural relativism where it is difficult to see beyond the lenses or filters of the dominant group and the assumption that this is how all people see things (Chang et al., 2009).

Forms of Communication

People communicate in many different ways. Paintings, music, poetry, and various forms of behavior, such as violence, may all be intended to communicate ideas or emotions to others. While in social work some of these different forms of communication may be encouraged or observed, the most often taught forms of communication revolve around nonverbal communication, or body language, verbal communication, and written communication. Generally, all forms of communication are expected to occur within an environment whereby the social worker demonstrates the core interpersonal skills of respect, genuineness, and empathy. These skills form the foundation of trust and rapport that are essential in building good social work relationships.

Content and Process

Social workers are required to pay attention to many different aspects of communication simultaneously. The content of communication involves what is being said, planned, or decided upon in an interaction. Words exchanged between people form only a part of the communication process. Social workers must also be in tune with what is called 'process.' Process involves all that is being communicated between people that is not being expressed directly with words and often gives clues about what is occurring in the relationship between the people involved. For example, when working with someone, a social worker may find that the other person appears noncommunicative in response to questions asked of them. The content of the session may be the questions that are posed and answers that are stated. The process of the interview may be more complicated. A social worker may have to ponder upon the meaning of the apparent noncommunication. If someone has been made to attend the session, and does not

want to be there, the client may be angry for having to be there and feel resentful toward the worker. The client may be experiencing anxiety at meeting the worker for the first time and may not want to say 'the wrong thing.' Alternatively, the client may come from a culture where direct communication is not the norm and they may feel quite at ease in the situation. It is very important for social workers to be aware of the process and what is being communicated by it, and it is also important for them to check out their assumptions about what may be going on. A very important clue to exploring process may be communicated through nonverbal communication or body language.

Nonverbal Communication and Body Language

Much of what is communicated between people is not done through the use of words. Bull (cited in Harms, 2007) claimed that 85% of communication is transmitted nonverbally. Two aspects of nonverbal communication are 'proxemics' and 'kinesics.' Proxemics is concerned with distance and how close people like to be to one another, while kinesics involves things such as movements, gestures, expression, and eye contact (Lishman, 2009).

Proxemics

A common exercise for social work students is to get them to experiment with something that is sometimes known as 'space bubbles.' Students are asked to stand face to face and have one move toward the other. The nonmoving student must tell the other student to stop when they start to feel uncomfortable with the other's proximity. This exercise is done in different variations, with students standing, with one sitting, etc. It is a very valuable exercise as it demonstrates that all people have different comfort levels regarding their personal space. It is important for social workers to be mindful of the space bubbles of the people they are working with. This is especially important when working with people who might have experienced physical or sexual abuse, or in situations of high tension or anxiety that may be escalated by people feeling that someone is too close. Similarly, it may feel hard for someone to establish trust if their social worker sits too far away with a large table between them. Context also plays a big role in determining what a desirable or acceptable distance is. What may be acceptable on a rush-hour tube or subway in a big city will not be the same as on a remote and unpopulated beach.

Kinesics

How communication is delivered involves the use of kinesics. Movements, gestures, and facial expressions are all used to communicate. How eye contact is maintained or avoided may communicate different things in different cultures or situations. Gestures may be used to reinforce messages (nodding, shrugging shoulders, yawning) or symbols such as the 'thumbs up' signal or clapping after a performance may also be used to communicate. Gestures or facial expressions may also be employed to communicate emotions, such as smiling when someone is happy, rapid hand movements when a person is excited, or crying when the person is sad. In all these instances, social workers need to be mindful that the symbols or things being communicated by kinesics are not universal and can be open to misinterpretation. Culture and context always need to be considered (see Lustig and Koester, 2013). While a large amount of our communication may be done nonverbally, much of it is done through the spoken word.

Verbal Communication

There are many aspects of spoken communication that social workers need to be aware of when working with people. The volume, tone, speed, and words used all communicate messages to people. Social workers must be mindful of their audience when communicating and may need to communicate their message in very simple terms at times, or, at other times, in very technical language. It is crucial for the social worker to remain genuine and respectful no matter the context.

Congruence between verbal and nonverbal communication is encouraged for clear communication. Congruence in this context means that all aspects of a person's being are communicating the same message. When there is non-congruence between verbal and nonverbal communication (for example, smiling as very bad news is delivered), people will be confused about what message the sender wants to send. The sender may then appear nongenuine or untrustworthy. Matching verbal and nonverbal communication gives the best opportunity of ensuring that the message that is being sent is being received as intended.

Written Communication

Social workers must also be able to communicate well in written form. Good writing and documentation are important for many reasons. Many authors have written about writing and documentation (see, for example, Conroy, 2012; Healy and Mulholland, 2012; Musson, 2011; Staniforth and Larkin, 2006).

There are certain standards that are often cited as being critical in most written communication. Writing should be clear; free of grammar, spelling, and punctuation errors; and as concise as possible, while communicating all that it needs to communicate. Long winding sentences and use of slang or jargon should be avoided.

Like all forms of communication, written communication needs to be done with an awareness of its purpose and context. The language and style used for writing a court document will be quite different from what may be required in clinical notes, or in an advocacy letter to support a client.

Social Work in the Digital Age

Modes of communication have shifted dramatically over the past 10 years. Social workers are now able to communicate with their clients by e-mail, text, or instant messaging; via social networking sites; or by modes such as Skype. While these modes of communication have offered many advantages to

clients who may at times be quite isolated, these changes have happened quickly and social workers and agencies have been left scrambling to develop best practice policies and guidelines around use of these technologies. Issues such as boundaries and expectations are of paramount importance to explore, as these technologies offer access to all parties on an instant and continual basis. One of social work's core principles regarding confidentiality is also at threat as these forms of communication offer little protection from hacking, or the forwarding or transmitting of these messages all over the world within nanoseconds.

E-mail communications are often deemed to be legal documents, like clinical notes, and must be kept for certain periods of time. As such, the same consideration should be given to their writing style and content. Instant messaging has a language of its own (text-speak) and social workers should be mindful at all times about the context of the communication in terms of the style used. In both cases, social workers need to establish some form of documenting these communications within client files.

Facebook, Twitter, and other forms of social media communicate vast amounts of information about people, and social workers may unwittingly be disclosing very personal information about themselves that clients might easily be able to access. Similarly, there are ethical issues in social workers being able to monitor their clients via their Facebook pages or Twitter accounts. Communication via such sites is often done in a very public manner and needs to be very carefully considered. Healy and Mulholland (2012) and Thompson (2011) have explored these issues in useful depth. Many organizations, such as the National Association of Social Workers (2005) in the United States and the British Association of Social Workers (BASW) (2012) have put out policy documents regarding the use of technology and social media. BASW's position is that social media should be treated like other forms of communication whereby "social workers should ensure they maintain appropriate professional and personal boundaries and take responsibility for recognising ethical dilemmas presented by the use of different types of social media" (2012: p. 4). The term 'E professionalism' is used to describe how one manages information posted on the various types of social media. In the online world, there is little distinction about what someone may post in a personal and in a professional context, as it is all likely to be easily accessed. Social workers are cautioned against posting anything that may have the potential to breach client or agency privacy, or that may leave them open to the questioning of their professional conduct (BASW, 2012). Once something has been posted on the Internet it cannot be taken back. Social workers need to keep up to date with emerging technologies and recognize the importance of maintaining their critical skills in terms of using all forms communication.

Common Communication Skills

The social worker's main job in their initial interaction with people is to start to establish a relationship where they demonstrate that they are trustworthy and capable and that they care about the person or people with whom they are engaging. Being able to demonstrate the core skills of warmth, empathy, genuineness, and respect is critical in this process, known as 'forming rapport' with someone. There are other skills, often known as microskills or interview skills, which form the foundation of basic communication skills training for many helping professions (Koprowska, 2010; Thompson, 2009). As with all skills, careful consideration needs to be given to their appropriate use, depending on context, culture, and the individuals engaged in the process.

Observation, Attending, and Listening

People want to feel that they have been heard and understood in their interactions with others. A social worker who is intent on working well with their clients will take the time, at the beginning of a meeting, to carefully observe how the other person is presenting. The person's body language, appearance, emotional responses and how they speak and respond to questions can all reveal clues about what may be going on for the other person, and how the worker may need to respond or alter their way of being or presenting themselves to best enable the person to feel at ease. Social workers often develop a 'sixth-type sense' in being able quickly to interpret what may be occurring through careful observation. It is important, however, that social workers check out their assumptions with their clients. The use of reflection skills described further in this text may be a good way to do this.

Attending skills show people that the other person is really there with them. Ivey et al. (2012) describe attending as the building block of good listening and use the acronym 'three Vs + B' in good attending. 'Visual/eye contact' refers to looking at people when talking to them. 'Vocal qualities' refer to displaying warmth and interest. 'Verbal tracking' refers to helping the client tell their story by not interrupting and staying on track. 'Body language' refers to being genuine, being oneself, and demonstrating warmth by the use of body language and facial expressions (2012: p. 57). Being aware of how different cultures may interpret these elements, or what they may see as being ideal in attending, is essential in attempting to form relationships. The skills of responding and reflecting can also be used to demonstrate that someone is attending and listening well in a relationship.

Responding and Reflecting Thoughts and Feelings

Empathy forms one of the essential building blocks of social work and welfare practice (Egan, 2014). Students are taught the differences between sympathy and empathy in their first few classes and then spend the rest of their careers improving on their empathy skills as they expand their range of life experiences and working relationships. Empathy is often understood to mean trying to understand, as best as one can, how someone else is experiencing their life or a situation within it. While it is impossible for someone to truly know what it is like for someone else, when an attempt is made to try to get as close as possible to that experience, the other person is likely to recognize the effort, and feel more understood and that they have been listened to (Howe, 2013).

One of the ways that empathy may be demonstrated is through reflecting the thoughts and feelings of the other

person. Students often worry that this reflection will sound stilted, or that they may 'get it wrong,' thereby showing that they are not competent. Indeed, if what the social worker constantly reflects back is not what they are being told or shown, then the client may begin to feel misunderstood. More often than not, however, the social worker can demonstrate that they understand what the client thinks and feels, and, if slightly 'off the mark,' this gives the client the opportunity to expand or clarify their experience.

Asking Questions

There are many reasons why social workers ask questions. Questions can be used to obtain information about someone, gain rapport, ensure understanding of something, demonstrate interest in someone, or learn what someone thinks or feels about something. One of the most direct ways of obtaining information about people is to ask them questions. As discussed previously, different cultures value different levels of directness and the content of what is appropriate to ask someone will also vary according to context and culture. Within a social work assessment, social workers elicit information through asking open and closed questions (Sidell and Smiley, 2008).

Open questions are often used when trying to open up communication and obtain information in a general way. They are designed to allow the person to answer as they would like to, or to expand upon an idea or topic. Open questions often begin with words such as 'how' or 'what.' Open questions can also be phrased more as statements or requests, such as, 'Please tell me more about what you were thinking at that time.'

Closed questions are more directive and usually allow the responder to choose between limited options. Closed questions can be used in an interview or meeting if the client is finding it difficult to stay on track, or when the interviewer requires particular information and needs to get it in a timely way. Closed questions may ask for a 'yes' or 'no' answer, such as, 'Did you go skating yesterday?' or may ask for information such as age, birth date, or other personal data.

Once information has been elicited, it may be necessary to clarify certain points or the meaning held for the person. The skill of clarifying can be used in these situations. Clarifying may also be thought of as a 'drilling down' or funneling technique, as more specific information is sought about something. Asking for specific examples, such as, 'What does your child do when you think that she is acting out?' or 'What makes you think that nobody likes you?' can help in this process.

Summarizing

Students new to social work often struggle in role-play or interview situations. Many find that they are inclined to 'freeze' as they struggle to come up with the next question to ask, or are uncertain about what direction to proceed in. Summarizing can be a magical tool in such situations. Being able to review with the other person what has recently been said or occurred in a conversation can serve several purposes. It allows the interviewer the space and time to gather their thoughts and feelings together. It demonstrates to the client that they have been heard and understood, or alternatively provides a space for information and its meaning to be corrected or clarified. It can also be used as a skill for getting back on track when an interview has meandered too far from its desired path. While summarizing may be a useful skill to use when an interview is filled with long silent spaces, the use of silence is, in itself, an important skill to develop (Ivey et al., 2012).

Using Silence

Being able to sit comfortably with silence and being able to understand its potential meaning are two qualities that often demonstrate an advanced level of social worker 'use of self' and confidence in practice. It is also equally important, however, to be able to gauge a client's level of comfort with silence and to respond appropriately. Observation of body language may provide important cues in this regard.

Silence can mean many different things. Some possible things that may be occurring during silence could be that the other person requires time to think or process an emotion; that they may be anxious, overwhelmed, or angry; that they may not be comfortable sharing something; or they may have said all that they want to say (Lishman, 2009: p. 94).

Specialty Areas of Communication

Working Across Languages

Working across different languages presents rewards and challenges for people in relationships. While body gestures, facial expressions, and body language can all help with understanding, bridging a linguistic divide demands certain awareness and skills. Samovar et al. (2013) provide some considerations regarding communicating with someone whose first language is not the same as the worker's. Being mindful of the process for the nonnative speaker is important in terms of information needing to be taken in, translated, considered, retranslated, and then responded to. This can be a very tiring process. Speaking slowly and using language that is simple and free of technical terms or jargon is useful. Attention needs to be paid to nonverbal behaviors as cues to understanding, and workers should check in periodically to ensure that they are being understood.

Working with People Who Have Hearing Impairments

It is also important for social workers to be aware of potential things that can help if working with someone who experiences sight or hearing deficiencies. When working with people who are hearing impaired, it is important to learn about the culture of the hearing impaired world. In many countries, such as New Zealand, sign language is an official language. Learning the language, or at the very least common signs, can show respect and a strong desire to form a relationship. Creativity can help: perhaps using pen and paper or using of images in communication. Ensuring that the client can see the mouth of the social worker who speaks slowly and clearly may also be useful. Allowing more time for meetings is also a good idea (Koprowska, 2010).

Using Interpreters

Social workers will often make use of interpreters when working with people who speak a different language from theirs. Whether translating from oral language or sign language, there are some important ways to facilitate communication and demonstrate respect. Social workers should consider matching issues in terms of who may be appropriate to translate. Gender, linguistic variations, religion, and the community that the participants come from may all need to be considered to ensure that there is sufficient trust in the translator (Moss, 2012). Social workers should be very clear in their communication, and not express too many key ideas prior to the translator translating. The social worker should address the client and/or family members, not the interpreter. The relationship to build is with the client, not the translator. The worker should plan for meetings with translators to take more time than other meetings (Koprowska, 2010).

Skills in Advocacy Work

With social justice being at the center of much of social work practice, at times social workers need to advocate strongly with, or on behalf of, their clients. This may require more directive and assertive communication than many social workers may be familiar or comfortable with. Advocacy texts (Bateman, 2000; Moss, 2012), the Internet, assertiveness training courses, or public speaking courses may be very helpful in gaining the skills and confidence to speak out as needed. Consideration again of culture and context is extremely important in learning how to best help get client needs met and it is also important that the reasons for the advocacy and the manner in which it is to occur are clear to both worker and client. Social workers need to ensure that they do not disempower their clients through the process of 'doing for,' however well intentioned they may be.

Conclusion

Social workers need to be able to communicate well. They must be able to communicate across many different situations, in different agencies, and with people who may be quite different from themselves. Without the ability to communicate well, the job of social work cannot be done.

There are many issues to consider when attempting to communicate well with people. Knowledge of self and other, awareness of culture, and the development of a concrete set of skills are all essential. The development of empathy and a critical and reflective stance can also help social workers enhance their communication skills. This article has attempted to explore these basic aspects of communication while recognizing that there are many other skills and processes that go into communicating well. Social workers need to equip themselves with the general and specific communication skills that will enable them to work well with whomever they meet. It is an important ongoing learning process.

Abstract

The concept of the 'two-step flow of communication' suggests that the flow of information and influence from the mass media to their audiences involves two steps: from the media to certain individuals (i.e., the opinion leaders) and from them to the public. Since the introduction of the two-step flow model and the opinion leadership concept, numerous studies have sought to advance both the understanding and applicability of these ideas to various areas from marketing and consumer behavior, to fashion, politics, and scientific innovations. However, the concept has been a subject of growing criticism, leading to a decline in the popularity and attraction of the original concept and almost to its total collapse. Nevertheless, the paradigm's 'fight for survival,' through a dynamic exchange of arguments, criticism, response, and debate, resulted in several modifications of the original model.

The concept of the 'two-step flow of communication' emerged from *The People's Choice*, the 1948 American voting study conducted by Paul Lazarsfeld and his colleagues at the Bureau of Applied Social Research of Columbia University. They observed that: 'ideas often flow from radio and print to opinion leaders and from them to the less active sections of the population.' Thus, the flow of information and influence from the mass media to their audiences was suggested as taking place in two steps: from the media to the opinion leaders and from them to the public. This model certainly called into question most of the assumptions of the 'powerful media' notion by revealing the limits of media influence while highlighting the role played by personal influence and especially by certain individuals – the opinion leaders. These ideas caught the attention and imagination of a new generation of researchers who opened up a new theoretical and empirical vista.

The Emergence of the Concept

Beginning with *The People's Choice*, Lazarsfeld and his colleagues were occupied with a series of panel studies on the role of mass communication in the making of decisions in various areas (voting, consumption, public issues, and others). The researchers focused on the impact of campaigns in the media and were surprised to find that interpersonal communication had a stronger impact on individual attitudes than the mass media alone. Moreover, they found that certain individuals were more central and influential in their groups, often acting as intermediaries between the mass media and the public. In comparison with the rest of the population, these individuals were found to be more exposed to the mass media. Thus, if personal influence was so important and if it was executed mainly by certain individuals who were more exposed to the mass media than the people they influenced, then it could be postulated that there was a two-step flow process from the media to the opinion leaders and from them to their followers. These intermediaries, called Opinion Leaders, could allow messages to pass through (backing them with their own personal authority), strengthen or weaken them, or block their passage entirely. This became the 'two-step flow of communication' model.

The most thorough and systematic examination of the two-step flow model and the notion of opinion leaders was the Decatur Study (after the community in which it was conducted). The study's procedures and findings were published in *Personal Influence* and represented one of the most impressive early documentations of the opinion leadership concept (Katz and Lazarsfeld, 1955). The research focused on four areas of decision making in daily life: marketing, fashion, public affairs, and movie selection. By isolating specific changes of opinion and identifying the influences that allegedly produced them, the researchers located the individuals who were mentioned most frequently as the source of influence. As this was a pioneering study, Katz and Lazarsfeld applied various methods and measures to locate and identify the opinion leaders. Briefly, there are two ways to locate opinion leaders in specific areas of influence. One is through the testimony of those whom they have influenced. The other is through a self-designation procedure in which respondents themselves are asked about their influence on others. To verify the 'self-designating' answers, the researchers requested the confirmation of the persons mentioned as advice-seekers. Two-thirds confirmed the contact and the topic. Although the researchers were satisfied with this 'validation,' it is far from being an acceptable measure of validity and indeed attracted later criticism.

The early studies on personal influence and opinion leadership resulted in several attributes related to opinion leaders (Katz, 1957). Let us briefly review the main ones: (a) Opinion leaders are found at every social level and in most areas of decision making, influence people from the same social level. (b) Opinion leaders are found in both of the sexes, all professions, all social classes, and all age groups. (c) Opinion leaders tend to be more involved in various social activities and social organizations and occupy central positions in their personal networks. (d) Opinion leaders are considered to be experts in their field, but this is informal recognition by close friends, relatives, co-workers, colleagues, and acquaintances. (e) Opinion leaders are more exposed to the mass media than nonleaders. (f) Opinion leaders are more interested, involved, and updated in the field in which they are influential. (g) Opinion leaders tend to be monomorphous, that is, they are usually experts in one area but rarely in various areas (i.e.,

polymorphous). (h) Opinion leaders manifest a specific communication behavior insofar as they are more involved in formal and informal personal communication than nonleaders. (i) Opinion leaders are usually well aware that they serve as sources of information and influence for others.

Since the introduction of the two-step flow model and the opinion leadership concept, numerous studies have sought to advance both the understanding and applicability of these ideas. Already by the early 1970s several hundred of these studies were available and the number has continued to grow steadily (for a review of almost 1400 of these studies, see Weimann, 1994). Thus, the 1960s and 1970s may be considered as the 'Golden Age' of the research on opinion leaders, yielding convincing empirical evidence of the opinion leaders concept in various areas: marketing and consumer behavior, fashion, politics and voting, family planning, science and scientific innovations, agriculture, and health care.

Criticism of the Model

The model's theoretical and practical appeal crossed the boundaries of disciplines, societies, and cultures. It attracted researchers from medicine to politics, marketing to family planning, AIDS prevention to clothing fashion, and agriculture to birth control. However, the concept has been a subject of growing criticism. The weaknesses and shortcomings of the original conceptualization of opinion leadership, and especially that of the two-step flow model, were exposed by several studies which combined theoretical, ideological, and methodological aspects (for a review, see Katz, 1987).

Theoretical Ideological Criticism

The media, according to the Columbia research tradition, were not as powerful as was assumed, once the public was found to be more active, less lonely, and less vulnerable. Defended by their selective consumption of the media and by the selective mediating function of the opinion leaders, people could fend off media influences and protect their attitudes, preferences, and values. The limited effects of the media as a central element in the opinion leadership and two-step flow concept became the main source for the theoretical-ideological criticism directed at this paradigm. Gitlin (1978), for example, rejected the two-step flow model and the functions related to the opinion leaders. The opinion leader is celebrated, he argued, because administrative researchers study proximate causes which are accessible to their patrons, the media organizations themselves, and the dominant values of the capitalist society. The ideological-theoretical bias of the two-step model, according to this criticism, is manifested in a set of assumptions: (a) *Commensurability of modes of influence:* the impact of the mass media was presumed to be comparable to personal influence, with the two 'forms of influence' regarded as functionally equivalent. (b) *Power as distinct occasions:* the measurement of influence by studying discrete incidents in a 'behaviorization of power.' (c) *Commensurability of buying and politics:* the areas of marketing, politics, fashion, and moviegoing were perceived as comparable within a single theory and measurable by a single method. (d) '*Change*' *as the sole dependent variable:* influence was identified by the occurrence of 'attitude change,' disregarding the case of reinforcement as an effect or the prevention of change as an effect. The latent power of the media to prevent changes and maintain the status quo should not be regarded as a residual category, but as a major function and a powerful effect.

Empirical-Methodological Criticism

The empirical-methodological weaknesses cited (see Weimann, 1982) include the following aspects: (a) Ignoring the evidence of direct flow from the media to the public. (b) Ignoring horizontal flow among leaders or among followers. (c) Ignoring the more than two-step flow, or 'longer chains of influence.' (d) The use of a crude dichotomy between leaders and nonleaders instead of applying continuous measures of leadership. (e) Standardization of measurement for information flow and influence flow. (f) Standardization of measurement across domains, disregarding the variance across domains of decision making. (g) The use of short timeframes, far from reflecting the long-term, cumulative impact of media messages.

The Paradigm's Fight for Survival

The wave of criticism led to a decline in the popularity and attraction of the original concept and almost to its total collapse. However, the paradigm's 'fight for survival,' through a dynamic exchange of arguments, criticism, response, and debate, resulted in several modifications of the original model.

The first amendment to the two-step flow of communication was the introduction of multistep rather than two-step flow. This allowed the inclusion of other optional directions of flow, such as horizontal (among leaders, among followers) and vertical (leaders to followers, active to inactive); direct (linking two actors directly) and indirect (linking actors through a third party or a chain of intermediaries); and downward (leaders to followers, media to public) and upward (from opinion leaders to media, followers to influentials, marginals to centrals). Another important modification was the introduction of continuous measures of opinion leadership and their validation (e.g., Noelle-Neumann and Csikszentmihalyi, 1992; Weimann, 1991, 1994).

Finally, the most promising development is the merging of the model with modern network analysis (Weimann, 1989). The developing theory and methodology of network analysis, combined with modern technologies of data processing, namely high-speed computers, special programs for sociometric data analysis, and such sophisticated mathematical procedures as matrix algebra and sociometric topology, has facilitated the study of large communities. It has also contributed to 'modernizing' the concepts of personal flow of media messages, opinion leadership, and flow of influence. Sheingold (1973) called for the use of social networks data as a 'resurrection' of the Columbia research agenda, and indeed much research on social networks in recent decades has focused on the role of influentials or 'centrals,' applying various structural measures taken from the network analysis procedure. These new developments have linked the two-step flow model with other theories and concepts, such as the Agenda-Setting process

(e.g., is there a two-step flow of agenda setting?; see Weimann and Brosius, 1994; Brosius and Weimann, 1996) and have thus contributed to revitalizing some of the notions of the two-step flow model.

Abstract

The notion of communicative competence refers to an individual's capability to communicate successfully in terms of both effectiveness (goal achievement) and appropriateness (acceptability in relation to context). The concept is related to debates about the nature of language and was developed by Hymes as a counter concept to Chomsky's proposal of linguistic competence. In contrast to this theoretical position, the concept of communicative competence sees language primarily as a means of communication, intertwined with other communicative media, coupled with and based upon other cognitive and social abilities, related to performance, and comprising all aspects of language including illocutionary and sociolinguistic knowledge, in contrast to being confined to grammar (in terms of syntactic, phonological, and semantic rules). The notion has also been developed within second-language teaching and interpersonal communication research. Depending on the specific focus of research, several constitutive components have been identified. It is a gradual concept, with communicative competence underlying performance and being built up with practice and experience. At the same time it may, depending on the communicative purpose, also be a function of more basic traits, states, and abilities (such as social relaxation, mind-reading abilities, and relevant kinds of knowledge). There is a vast amount of research on different aspects of communicative competence, including its implications for personal life; its components and measurement depending on setting and specific communicative function; the development of communicative competence, methods of improvement, and the processes involved in competent communicative behaviors.

The term 'communicative competence' refers to an individual's capability to communicate successfully and underlies actual communicative behavior in concrete situations. The notion of communicative competence comprises, thus, both knowledge of the communicative means of a community – as reflected in judgments of acceptability – and the ability for its use.

The concept emerged in the context of debates in the early 70s of the twentieth century, about the nature of language and the proper way to study it; and is thus closely related to fundamental theoretical issues, such as theory of language and the relationship between language and communication. Further developments in the scientific history of the notion of communicative competence occurred in conjunction with research on interpersonal communication and social interaction focusing on face-to-face settings and aiming at identifying the relevant dimensions of communicative competency in social encounters. Other models of communicative competence, in terms of components, stem from research in second language teaching and learning. The concept is thus of great practical relevance – also in respect of other areas, such as language development in children; specific communicative functions, such as persuasion, arguing, negotiations, emotional support, etc.; social settings, such as parenting, healthcare, educational settings, etc.; and intercultural encounters. There is now a substantial and diverse research literature on different aspects of communicative competence from different scientific fields, including communication sciences, sociolinguistics, psycholinguistics, psychology, language testing, speech disorders, education, management, and social work – even though definitions of what constitutes communicative competence differ widely.

The Concept of Communicative Competence in Historical Perspective

Diversity of Speech and Knowledge of Language

The term 'communicative competence' was introduced by the sociolinguist Dell Hymes (1972) and independently also by others, e.g., Sandra Savignon (1972) in the area of second language teaching, involving the recognition that mastery of a language comprises a wider range of abilities than grammatical knowledge (cf Hymes, 1992). While having referred to 'competence' in the context of communication previously, Hymes coined the expression 'communicative competence' specifically as a reaction to Noam Chomsky's definition of 'linguistic competence' and his fundamental distinction between 'competence' and 'performance.' "When 'Aspects of Syntax' appeared […] (1965), a first reaction was that Chomsky could not really be serious in dividing the world of language between 'competence' and 'performance', while defining the former in so limited a fashion" (Hymes, 1992: 32).

In his endeavor to lay the foundations for (the syntactic component of) a generative grammar – which is supposed to be able to generate, with a limited system of rules, all of a language's indefinitely many sentences out of structural descriptions – Chomsky (1965) maintains that "[l]inguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors (random or characteristic) in applying his knowledge of the language in actual performance" (p. 3). While a language's grammar in this theoretical approach is understood as description of the immanent

linguistic competence of the ideal speaker-listener, linguistic competence is also assumed to underlie a real speaker-listener's linguistic performance. However, according to Chomsky's conceptualization, linguistic use or performance in concrete situations is just a poor reflection of linguistic competence, as natural speech is full of wrong starts, rule deviations, midsentence changes, etc. Thus, for Chomsky, linguistic competence is the individual's knowledge of one's language, which is intuitive, tacit, and only in part accessible to consciousness, and which allows one, in principle, to understand any sentence of one's language and produce a sentence expressing this idea. For the sake of scientific inquiry it is assumed that it is homogeneously represented in the minds of the members of a speech community, abstracting from all variation such as styles or dialects (cf Chomsky, 1980).

This dichotomy of competence/performance is rejected by Hymes (1972) along with the idea of a perfect or even homogeneous competence in a language, its narrowing to aspects of grammar, and its isolation from sociocultural features (for arguments of other authors put forward in the controversy of the time, see Hymes, 1972, 1992). One concern of Hymes' approach is to explain the communicative differences between groups of children in order to provide support for children in need, for which a linguistic theory in terms of Chomsky's conceptualization seems inapplicable. Hymes argues that "[t]o cope with the realities of children as communicating beings requires a theory within which sociocultural factors have an explicit and constitutive role" (1972: 271). One starting point in his considerations is the situation of individual or societal bilingualism, in which fluent speakers often regard their languages as differing in communicative adequacy depending on situation and function. This observation can be extended to varieties of a language. More generally, there is a combination of diversity and differential competence within communities. In addition, competencies in production and reception may differ, and what is and is not acceptable and intuitively correct in linguistic grammar may depend on social and contextual constraints. Altogether, the term 'communicative competence' chosen by Hymes places an important role on the heterogeneity of speech communities, differential competencies, and sociocultural features in a linguistic theory.

Another important aspect of communicative competence, in this sense of the word, is that a child learning a language acquires not only knowledge of the grammar, but also of appropriateness. This involves competence of when to speak, what to say to whom in what situations, and in what manner, the mastery of a range of speech acts, and integration with other communicative means, as well as attitudes toward language. According to Hymes, there are several parts of communicative competence, of which grammatical competence is just one. There are several systems of rules underlying linguistic behavior, which are reflected in the judgments that language users are able to make. Instead of a dichotomy, Hymes proposes the following four types of judgments which must be recognized in a linguistic theory, formulated sufficiently generally to integrate language with other means of communication (p. 281):

1. Whether (and to what degree) something is formally *possible*;
2. Whether (and to what degree) something is *feasible* in virtue of the means of implementation available;
3. Whether (and to what degree) something is *appropriate* (adequate, happy, successful) in relation to a context in which it is used and evaluated; and
4. Whether (and to what degree) something is in fact done, actually *performed*, and what this entails.

The Nature of Language and Its Relation to Communication

Within language-focused debates, the controversy between accounts in terms of linguistic competence versus communicative competence is closely related to the fundamental question of what language is – forming the core of the theory of language. This, in turn, bears on issues such as: How is language acquired? How did language evolve and change? What is the function of language? How is it related to (other forms of) communication?

So, the description in terms of homogeneity versus heterogeneity; perfect competence which can only be impaired in performance versus differential competence reflected in language use; grammar as the core of human language capacity versus language as a range of abilities integrated with other modes of communication is not, in both approaches, simply a matter of different focus or abstracting away from certain aspects for simplification in scientific study. It is deeply rooted in fundamentally different ideas of what language is and how it should be studied.

'Linguistic competence' is seen as a characteristic of the human mind, whose acquisition by a child is based on an innate theory of language that allows them to construct or select a generative grammar out of an imperfect section of a language encountered, which they can use as primary linguistic data for testing hypotheses about the structure of the language. In this view, children acquire the infinite ability to create or understand sentences, (tantamount to linguistic competence) with ease and in a short time, because they have prior, innate knowledge of a universal grammar. Universal grammar, in this account, is assumed to express the profound regularities of all language capturing the creative aspect of language use (Chomsky, 1965) and to provide the innate predispositions or constraints underlying language development (Hauser et al., 2002). Language is mainly conceived of as an internal instrument for thought, of which only part reaches consciousness, and relative to which all usages that depend on externalization, including communicative functions, seem peripheral. A more recent way to put this is as a distinction between language as a communicative system and language as the internal component with underlying computation (Hauser et al., 2002). Accordingly, a distinction between the faculty of language in the broad sense (including a sensory-motor system, a conceptual-intentional system, and the computational mechanisms for recursion) and the faculty of language in the narrow sense (including only recursion) is made, and it is hypothesized that the latter is the only uniquely human component. According to this conception, the computational component is the core of the human language capacity; it links the sensory-motor and the conceptual-intentional systems, and it (i.e., language) may

have emerged without selection pressure, for reasons other than the adaptive evolution of communication.

'Communicative competence,' on the other hand, is seen as a complex range of linguistic abilities underlying the capacity to communicate successfully, not autonomous but intertwined with other cognitive (and maybe also motivational and emotional) processes, and being integrated with other means of communication. In this view, children acquire language in social interaction under important sociocultural conditions and in a social world, with true learning taking place and based on more general cognitive mechanisms instead of inborn grammatical principles (see, e.g., O'Grady, 2008). Variation is a central aspect of language, which not only adds to its structure but partly constitutes it. Language is intricately related to language users' cognitive constraints, such as learnability and processability. Both limitations of memory, articulation, attention etc., and social processes contribute to the actual form of linguistic structures (cf Hymes, 1992; for more recent approaches emphasizing the selectional pressure from generations of language users, the repeated construction and interpretation of utterances in social interaction, and choice from a pool of linguistic variation, see Christiansen and Chater, 2008; Hruschka et al., 2009). More generally, according to this account, language cannot be defined as linking meaning and sound. It is conceptualized as comprising a huge variety of speech acts and communicative functions and being related to communicative behavior and social life. The social dimension is constitutive for the linguistic level of speech acts, specifying whether a specific grammatical sentence is meant as, let's say, a statement, an offer, or a threat, as well as for the rules of use that determine what linguistic forms are appropriate under what conditions.

In addition to the different answers to the issue of the nature of language and other questions related to it, Chomsky's linguistic competence and Hymes' communicative competence take also different epistemological stances. Accordingly, the methodological positions and the ideas of how scientific inquiry should proceed within linguistic research differ considerably. The concept of linguistic competence belongs to a decidedly rationalist approach relying on intuition, introspection, and logic with an explicit rejection of objective data, leading to the situation that the intuitive, tacit, only partially accessible knowledge of language users is the only source for determining the adequacy of a linguistic theory in this concept. In contrast, the concept of communicative competence following rather an empiricist approach to scientific knowledge, attempts to draw on a variety of data collected with quantitative as well as qualitative methods, with convergence of different kinds of data used for complementation and the strengthening of evidence.

Another counter-model to Chomsky's 'linguistic competence' was the concept of 'communicative competence' developed by the social philosopher Jürgen Habermas (1970) in his endeavor to lay the foundations for a revision of sociological role theory and an analysis of the 'logic of explanation.' According to his theory, the ability for argumentation and discourse is a precondition for acting rationally and discursively reaching consensus and understanding, based on the communicative competence of interlocutors. Habermas criticizes the monological nature of the concept of linguistic competence constructed in the mind of speakers, prior to all communicative experience. His concerns relate mainly to the semantic component of generative grammar, specifically the conjecture of a priori universal, semantic meaning components constraining the possible concepts in mind, which is incompatible with the assumptions of (1) semantic universals being part of intersubjectively produced cultural systems (critique of monologism); (2) semantics reflecting specific realms of experience (critique of apriorism); and (3) more global representations of nature and society (critique of elementarism). Habermas holds that "[i]t is not enough, to understand communication as an application – limited by empirical conditions – of linguistic competence" and that "[o]n the contrary, producing a situation of potential ordinary language communication belongs by itself to the general competence of the ideal speaker" (p. 138). While Habermas, in contrast to Chomsky, emphasizes the role of intersubjectivity, regarding it as linguistic, his theory is similar to Chomsky's concept in referring to an 'ideal' speech situation: "[C]ommunicative competence relates to an ideal speech situation in the same way that linguistic competence relates to the abstract system of linguistic rules. … Communicative competence is defined by the ideal speaker's mastery of the dialogue constitutive universals irrespective of the actual restrictions under empirical conditions" (pp. 140–141).

Mastering a Second Language

The question of what it means to master a language is also of central importance to second language education. The concept of communicative competence entered this field independently of Hymes' proposal, in connection with communicative approaches to language teaching, but started soon to be discussed with reference to his theoretical approach and arguments. It generally recognizes the need for good communication skills in the language to be acquired and the necessity of using language (at least part of the time) for communicative purposes, in order to acquire this competence. The term may refer to the ability to participate in linguistic interaction and the importance of using communicative settings, or it may more specifically refer to the social rules and knowledge of appropriateness depending on context, situation, and purpose.

An influential model of communicative competence within the context of language teaching was developed by Michael Canale and Merril Swain (1980). It includes three main competencies: grammatical competence, sociolinguistic competence, and strategic competence. Grammatical competence includes the knowledge of lexical items and morphological, phonological, semantic and syntactical rules. Sociolinguistic competence refers to rules of appropriateness and of discourse, while strategic competence comprises the means to compensate for breakdowns in communication. In all three components of communicative competence, differential probabilities of occurrence are assumed to apply.

Based on this and other research, a refined model of the components of communicative language ability was constructed by Lyle Bachman (1990) as theoretical framework for language testing. Its main three components are: (1) the knowledge of the language in terms of the set of components needed for communication via language, called 'language

competence'; (2) the capacity for implementing those knowledge components in communicative use, called 'strategic competence'; and (3) the ability to actually execute language in terms of 'psychophysiological mechanisms.' The main components are, in turn, comprised of more specific components that can, again, hierarchically be subdivided into subcomponents. In language use, components interact with each other and also with features of the communication situation. Language competence includes both knowledge of how to relate and organize linguistic symbols (in terms of both grammatical and textual competence components) and knowledge of how to make utterances acceptable in certain communication situations (in terms of both illocutionary functions and sociolinguistic appropriateness). Strategic competence is related to the dynamic character of language use emphasized in this approach. Different from Canale and Swain's model, the term refers not only to compensatory communication strategies here, but more generally to the mechanisms involved in situation assessment (including the interlocutor's capabilities and achievement of communication goals) as well as language-planning and language-executing processes in productive or receptive language use. The execution itself depends also on psychophysiological mechanisms as the third main component of the model.

Communication and Interpersonal Interaction

A different approach to communicative competence has been taken within the literature on social interaction and interpersonal communication. In an attempt to analyze good or effective conversational behavior in everyday face-to-face interaction, John Wiemann (1977) constructed a model of communicative competence composed of the dimensions of (1) affiliation/support, (2) social relaxation, (3) empathy, (4) behavioral flexibility, and (5) interaction management skills (including conversational turn-taking, topic control, and attention.) These dimensions were tentatively proposed on the basis of three previous approaches to interpersonal competence: Goffman's self-presentation, Argyle's social-skill, and the training-in-social-relations approaches, and put to test in an experimental study. An important criterion for communicative competence in this conception is whether a conversational encounter is evaluated positively by other communicative participants. Results revealed a strong, positive, linear relationship between interaction management and communicative competence, and also positive correlations between perceived competence and other components of the model. According to these results, the competent communicator in face-to-face conversational encounters is empathic, supportive, and relaxed; as well as capable of adapting to situational changes and securing smooth speech turns.

The quality of interpersonal communication, with a focus on dyadic, face-to-face interaction is also the topic of Brian Spitzberg and William Cupach's (1984) model of 'interpersonal communication competence.' However, the scope of their theory is much broader than Wiemann's confinement to conversational encounters, with communication competence being defined as "the ability to engage in appropriate and effective interpersonal interaction" (p. 14) relevant in a multitude of interpersonal events, such as interviewing, persuasion, negotiation, conflict management, and social conversation. Accordingly, the theory draws on diverse historical precursors in rhetorics, psychiatric approaches to social functioning, and research on marital and other interpersonal relationships. It bases itself on a review of prominent theoretical approaches to competence in communication – including social-competence, interpersonal-competence, and relational-competence models in addition to the approaches of Chomsky, Habermas, and Hymes to linguistic versus communicative competence – and a discussion of key assumptions in research on communication competence. While all of these approaches deal with certain aspects of socially communicative behavior, some of them are concerned with the communicative behavior itself, focusing on appropriateness; some are concerned with the outcomes of communication, focusing on effectiveness; and some focus on the relation between communication processes and functional outcomes. Arguing that both appropriateness and effectiveness are integral to competent communication, Spitzberg and Cupach identify four global constructs of communicative behaviors involved: (1) 'Interaction management' is the ability to structure and maintain interpersonal interaction smoothly, brought about by behaviors such as topic-initiation, turn-yielding, and turn-taking signals, use of questions, sentence completion, head nods, and eye-contact initiation. (2) 'Altercentrism' concerns other-oriented behaviors, such as topic support, compliments, eye contact, head nods, body lean, smiling, and other manifestations of empathy, supportiveness, attentiveness, politeness, and approval. (3) 'Expressiveness' refers to the vividness of facial expression, vocal modulation, and gesturing, and the ability to articulate meaning using a variety of means, including clarifications, requests, humor, and expressions of opinions or feelings. (4) 'Social relaxation' is conceived of as the absence of indications of social anxiety, such as crossed arm or legs, eye contact avoidance, arm posture rigidity, speech nonfluencies, tense voice, and speech blockage.

An attempt to explicate communicative competence in terms of specific communication theories has been undertaken by Stephen Wilson and Christina Sabee (2003), dealing with five classes of communication theory: expectancy theories, attribution theories, goals-plans-action theories, hierarchical message production theories, and dialectic theories of relationships. While these theoretical approaches offer different perspectives on communicative competence and consider different aspects, a more general approach taken by a number of authors is to focus on core criteria that are most general and comprehensive and provide a common framework for various theories and empirical studies (see, e.g., Rickheit et al., 2008; Spitzberg, 2003).

The Essence of Communicative Competence

Putting Together Social and Linguistic Perspectives

Even though research on communicative competence has dealt with disparate aspects of able communication, there is a large overlap in concerns and basic ideas. A main distinction can be drawn between studies and theories that focus on social

encounters – both in terms of the type of communication situation studied and in terms of the processes involved in social perceptions and relationships – and between studies and theories that focus on language as a central and sophisticated means of communication, often intertwined with other communicative mediums.

The social perspective on communicative competence is closely related to concepts such as interpersonal, social, or relational competence, with terms chosen not always being indicative of the exact scope or issue of a study or theory. Some of the approaches undertaken from this perspective, address other-oriented and interaction-management characteristics related to social nonanxiety, emotional intelligence, and social judgment. Others aim at describing the essential elements of successful interpersonal communication, in terms of internal judgment and planning processes or mutual influences. The research on social interaction skills has been reviewed in several overview articles and comprehensive handbooks (e.g., Greene and Burleson, 2003; Knapp and Daly, 2011).

The linguistic perspective on communicative competence, also referred to as communicative language ability by Bachman, is devoted to an understanding of what is involved in the use of communicative language and what is needed in order to communicate in a given language, subscribing to an expanded view on language and language proficiency that takes into account the context of language use and the question of how language is used to achieve particular communicative goals and to do things. This includes all the kinds of knowledge required to use language, including linguistic form, textual as well as illocutionary linguistic functions, context in terms of both discourse and sociolinguistic situation, and sociocultural factors. An overview of the state of knowledge is given in the 'Handbook of Communication Competence' (Rickheit and Strohner, 2008), which appeared in the series 'Handbooks of Applied Linguistics.'

Both interpersonal and linguistic competencies contribute to communicative competence, with some factors enabling others to be brought to bear, some abilities making up for each other, and further aspects being indispensable depending on the specific communicative situation, such as empathy for providing emotional support or textual competence for giving a public speech. Most importantly, linguistic and social perspectives on communicative competence converge in similar views on the conceptual importance of communication in theorizing, in regarding the capacity to communicate skillfully as a kind of overarching goal of individual development, in seeing communicative competence as a graded concept, and in the dual character of communicative competence implying both effectiveness and appropriateness.

Effectiveness and Appropriateness as Core Criteria

While different approaches have put different emphases on effectiveness or appropriateness considerations, at least one of both definitional criteria plays a role in virtually all of them. Moreover, in contrast to early distinctions, many more recent approaches to communicative competence consider both elements as constitutive (see Rubin, 1990). Both norms and intentions guide our communicative behavior in production and interpretation; both appropriateness and effectiveness characterize communicative competence (see the reviews given in Rickheit et al., 2008; Spitzberg, 2003).

In production, effectiveness is goal accomplishment – the ability to achieve communicative goals, to get meaning across, to say what one means to say, to perform actions, to influence others, to form relationships, to express oneself, etc. Multiple goals may be pursued simultaneously; on the one hand they are often hierarchically embedded, on the other hand a main goal underlying a communicative act may be accompanied by secondary goals (such as maintaining a good relationship to the addressee). In some situations, efficiency – the ability to achieve communicative goals with less effort and resources – may be additionally relevant.

In reception, effectiveness concerns the ability to infer a speaker's meaning. This may, e.g., imply an understanding of whether an utterance is meant literally or ironically, what speech act a speaker wants to perform with an utterance, and whether, let's say, an ironic utterance is meant to be a critique or simply a joke. In both production and reception, effectiveness implies the knowledge of how language (or another communicative medium) is used to achieve particular communicative goals, and how to implement this knowledge in actual language use. In Bachman's model of communicative language ability, effectiveness is described in terms of both illocutionary functions and strategic competence (including the capacity to access what information is needed, and what language resources are available, for achieving a communicative goal, to retrieve the relevant items from language competence, and to form a plan to achieve this communicative goal).

Appropriateness concerns sensitivity to context – the ability to choose linguistic and other communicative means in accordance with norms of acceptability and legitimacy, which may depend on situation, function, the speaker's identity, and sociocultural factors, or to assess the communicative means chosen by another speaker accordingly. It involves sensitivity to differences in dialect, register, or other types of variety, judgments of probability of occurrence, stylistics, politeness, and a knowledge of the culturally, situationally, and textually specified rules of who can speak when, how to address other people, what topics are appropriate, what level of politeness is required, how to time conversations, how to end an encounter, how to regulate spatial proximity, touch, or direct gaze, etc.

In Bachman's model of communicative language ability, the component of sociolinguistic appropriateness captures several linguistic aspects of this criterion – focusing on varieties, registers, naturalness, and cultural meaning extensions. More broadly, appropriateness means the ability to relate to social and interpersonal norms or expectancies based on knowledge of these sociocultural factors. Usually this implies an avoidance of their violation; however, sometimes, overriding or altering existing rules may be appropriate communicative behavior, and some deviations from expectancies may have positive outcomes, as addressed by expectancy theory.

While neither effectiveness nor appropriateness are reducible to each other, they are also not independent from each other. On the one hand, the appropriateness of a communicative behavior might well depend on the communicative function performed; and on the other hand, the achievement of

a communicative goal might depend on the adherence to sociolinguistic rules. At times there may even be contradictions between both criteria, with one criterion constraining the possibilities of communicative behavior according to the other, and communicatively competent behavior being a function of a trade-off between both.

Adaptability

A fundamental aspect of communicative competence – related to both effectiveness and appropriateness – is adaptability, the ability to adapt to different conditions, functions, tasks, situations, communication partners, and contexts. It relates to appropriateness inasmuch as that is a function of social situation, communicative function, setting, and cultural context. It relates to effectiveness, as the means to achieve a communicative goal may depend on the interlocutors' abilities, interests, and other preconditions, and may need to be adapted to changing circumstances.

Mutual adaptation is one of the most pervasive phenomena in interactive communication (for reviews, see, e.g., Burgoon et al., 1995; Vorwerg, 2013). During interaction, people converge in their communicative behavior at many levels, including body posture and movements, aspects of linguistic content, gaze, proximity, voice features, pronunciation, linguistic elements and structures. Moreover, convergence in communicative behaviors is related to the quality of communication. It can also be assumed that the tendency to adapt to each other in communication contributes to the emergence of sociolinguistic patterns. Adaptation is also required to adapt in reception, in order to be able to understand communication partners who use communicative forms that do not belong to one's own active repertoire. More generally, the ability to adapt to a communication partner in production and reception depends on the variability of linguistic and other communicative means (Vorwerg, 2013), which may again be related to the dimension of expressiveness in Spitzberg and Cupach's model of interpersonal communication competence. The ability to choose aptly between different variants and to use them in novel, creative ways may add extra value to the quality of communication.

The Nature of the Concept of Communicative Competence

Most research treats communicative competence as a construct – an explanatory concept that has no direct observable referent but is indirectly observable in terms of manifestations or indicators (or, in other conceptions, is based on observables). While individual definitional proposals for communicative competence range at the extremes from treating the term as a theoretical concept whose meaning cannot be specified outside the context of specific theories (Wilson and Sabee, 2003) to describing it as the quality of interpersonal-skill enactment (Spitzberg, 2003); the most consistent and, arguably, the most fruitful conceptualization is to define communicative competence as the ability to communicate effectively and appropriately underlying actually observable behavior. This forms the basis for clarifying its relation to other concepts, such as performance, knowledge, and skill.

Communicative competence can thus be described as an individual's potential to perform communicative behaviors successfully in terms of goal accomplishment and acceptability. This capacity underlies (and also predicts) actual performance in communicative situations, which conversely can be regarded as the manifestation of this underlying competence. Accordingly, communicative competence comprises both the knowledge needed to engage in communication, and the ability to implement this knowledge. This knowledge includes – in addition to rules or regularities, factual knowledge, and individual memories – a range of skills, which can be considered as procedural knowledge, i.e., knowing how to, which in itself incorporates the ability for use. Thus, communicative competence is partly constituted by social, verbal, and other communicatively relevant skills, i.e., the capacities to perform complex social, verbal, or other patterns of behavior smoothly and adaptively. The specific use of the term 'skill' may vary between authors, from narrowing it to more elementary behaviors, such as asking a question or making eye contact, that may or may not be instrumental in a communicative context (see Spitzberg, 2003); to broader attempts to identify the key abilities involved in particular communication competencies in terms of skills, such as negotiation skills, arguing skills, or emotional support skills. However, the idea that a multitude of interrelated skills contributes to communicative competence seems to be generally agreed upon.

Communicative competence is related to other competence concepts. There is partial overlap with social, intersubjective, and interpersonal competence. Theory of Mind as a component of intersubjective competence, for example, is relevant in inferring a speaker's meaning. Sociolinguistic and metaphoric (or other figurative) competencies can be regarded as forming part of communicative competence, with pragmatic competence, as an intermediate level comprising both of them, in addition to knowledge employed in speech acts and cultural references. Finally, intercultural competence is a specific form of communicative competence required for communication across cultures.

Areas of Empirical Research

Communicative competence is a fruitful research field, as evidenced by the vast number of studies devoted to a variety of empirical questions. One area of research concerns its impact on different areas of an individual's life. Results show that communicative competence is related to the maintenance of personal relationships, including marriage, romance, and friendship; and to social embeddedness versus loneliness; and therefore also to health and happiness, which both depend on a person's social connections. Abilities in a range of communicative functions are also important for academic and occupational success.

Another area of research investigates the components of communicative competence – depending on settings and functions. This includes also research on the assessment and perceptions of communicative competence, the indicators of good communication, and the levels of particular communicative abilities present in certain populations. The relevance of communicative skills may vary between different settings,

such as private versus organizational settings, dyadic face-to-face situations, individual correspondence, social media, group communication, or public situations, symmetric versus asymmetric relations, classroom settings for language practice, health-care contexts, job interviews, etc. The involvement and importance of particular components, such as responsiveness, anticipation, means of remediation, immediacy, verbal clarity, listening skills, clear articulation, vocal variety, expressions of acceptance or concern, structural soundness of arguments, mind reading, etc., varies also between different communicative functions, such as persuasion, negotiation, arguing, instruction, emotional support, socializing, conversation, social problem solving, public speech, etc. Empirical questions in this context are also the generalizability and transferability of communicative skills acquired in a certain situation (such as the classroom setting), and the degree of consistency of communicative competence across communicative functions or settings, possibly related to communicative adaptability and behavioral flexibility (cf Spitzberg and Cupach, 1984) or very basic underlying abilities or traits.

Other research focuses on the development of communicative competence in childhood and adolescence, and beyond, as well as on the acquisition of communicative competence in a second language, and on interventional approaches. Developmental issues addressed include the emergence of communicative intentions, prelinguistic communication, the development of mind reading related abilities – such as intention reading, joint attention, understanding others' first- and second-order beliefs, and metarepresentations – and their relation to linguistic communication, the mastering of speech acts, the acquisition of linguistic variation, the understanding of figurative language, conversational abilities, the development of style and appropriacy judgments, the role of parenting skills, etc. (for introductory overviews, see Foster-Cohen, 1999; Hoff, 2009; Rickheit et al., 2008). Interventional approaches concern both training programs developed for specific communicative abilities and functions (such as arguing, negotiation, emotional support, public speaking, or marital communication), and diagnostic tools and therapeutic methods for the treatment of language and communication impairments (see, e.g., Greene and Burleson, 2003; Rickheit and Strohner, 2008).

A further area of research is focused around the processes involved in message production and message reception, which imply communicative competence. Research fields include the psycholinguistics of dialogue and mutual adaptation, cognitive pragmatics, social cognition, and psychological approaches to communication theory. Central questions of research are how interlocutors manage to coordinate their talk in interaction, what specific processes subserve the conveying of the intended meaning, conversely what is involved in inferring the speaker's meaning, also what mental representations and knowledge structures underlie competent communicative behaviors, and how nonverbal behaviors are generated and interpreted in face-to-face interaction (for a review, see Rickheit et al., 2008).

A novel research field is communicative competence in the electronic age, devoted to studying skills involved in communication in electronic environments, such as text messaging, mobile communication conversation, or social networking. As communication depends on the media used, the two fundamental issues involved are what constitutes media competence itself and how the available media influence communicative processes. A model of mobile communication competence proposed by Bakke (2010) and based on factor analyses includes six constructs: willingness to use, mobile preference, asynchronous communication, efficacy, affect, and appropriateness. Studies on the effects of mobile communication technology have shown that it has changed interpersonal coordination patterns, leading, among other things, to increased social face-to-face interaction; that it has brought about a growth in mobile work, rendering the term 'workplace' outdated for many; that it has changed relational communication, among other things, by adding a new layer of privacy through text messaging; and that it strengthens social network ties (see Campbell and Ling, 2008). The features, limits, and affordances of the media themselves (such as character length and screen sizes), as well as their social and communicative consequences (such as a lowered threshold for communicating, more permanent and closer connectedness, flexibility in communication, and microcoordination) have also lead to new forms of communicative means and conventions at all levels of communication (e.g., linguistic forms, nonverbal expressions of emotion, ways to perform speech acts, forms of address, turn-taking, rules of when to address whom about what), which concern both the efficiency and the appropriateness of communication.

Abstract

Following the different interpretations of the word communism, researchers concentrated their work on (1) the idea of social and political thought, (2) the political movements, or (3) state political systems. Research on communist political movements and systems of state has been seriously complicated due to changes in time and space since both have existed for almost 100 years and have manifested themselves in different zones of the world, most intensively, however, in Europe and East Asia. At present, communist parties exist only in a few countries and the communist systems exist exclusively in the Far East and in Cuba but with many changes to the previous form.

Introduction

The notion of communism has been used in three different ways. First, since antiquity communism has been referred to ideas relating to advanced forms of socialism advocating the need to organize societies as communities owning means of production and consumption. Second, the term communism signifies political movements with 'bolshevism', an extreme faction of Russian social democracy, as their protagonist since 1903. Third, communism denotes a political and socioeconomic system of state introduced for the first time in Russia in the year 1917.

Following the three different interpretations of the word communism, researchers concentrated their work on:

1. the idea of social and political thought,
2. political movements, or
3. state political systems with particular emphasis on dictatorship (totalitarian ideas), and economic systems, especially nonmarket economies, planned economies, and autarchies.

Research on communist ideology, political movements and systems of state has been complicated seriously due to changes in time and space since both have existed for almost 100 years and have manifested themselves in different cultural zones of the world, most intensively, however, in Europe and East Asia. Only in the last years of the Soviet Union were attempts made to approach the problems in all three spheres during the whole of the time and in all zones of the world. (Service, 2007; Priestland, 2009).

The Idea

The ideas of communism have surfaced since antiquity and have been present throughout the Middle Ages, the Renaissance, the Enlightenment, and the French Revolution. The proponents of communism resorted to moral or economic arguments advocating the need to organize societies as communities owning means of production and consumption. These ideas were adopted by some socialists in the nineteenth century. Marx and Engels published their '*Communist Manifesto*' (1848). To substantiate his ideas, Engels drew on the then studies on primitive societies as representative of classless communities (the natural state of society was disrupted by the division into social classes).

However, the notions of socialism and communism were sometimes used interchangeably in the nineteenth century. When social democracy developed in many countries, socialists hardly ever used the notion of communism, whereas anarchists resorted to it occasionally (Kropotkin's anarchocommunism).

Communist ideas have acquired a new meaning since 1918. They became equivalent to the ideas of Marxism–Leninism, that is, the interpretation of Marxism by Lenin and his successors. Endorsing the final objective, namely, the creation of a community owning means of production and providing each of its participants with consumption 'according to their needs', they put forward the recognition of the class struggle as a dominating principle of a social development.

In addition, workers (i.e., the proletariat) were to carry out the mission of reconstruction of the society. Conducting a socialist revolution headed by the avant-garde of the proletariat, that is, the party, was hailed to be a historical necessity. Moreover, the introduction of the proletariat dictatorship was advocated and hostile classes were to be liquidated.

Some researchers emphasized a quasireligious element of the communist (and earlier socialist) ideas (Muravczik, 2002). In the following decades, communist ideas have been subject to dogmatism, on the one hand, and, on the other, to current political pressures. Paramount importance was attributed to the 'classics', namely, to Marx, Engels, and Lenin, as well as Stalin during his rule. It was only the later 'classics' (i.e., Lenin and Stalin) who were believed to be entitled to correct and amend the views of the earlier 'classics'.

The communist ideology was expanded to include new components such as an exemplary role of the USSR and 'the principle of exacerbating the class struggle parallel to the building of socialism' (Stalin), which was called into question after 1953. In the years to follow, the ideas of a peaceful coexistence of socialism and capitalism as well as that of a peaceful transition to socialism were added.

Some differences have surfaced between communist ideas endorsed in the USSR and the Soviet bloc; in Yugoslavia, where social and economic aspects of self-government were regarded

as significant features of the communist ideology; and in China, where Maoism became a revolutionary ideology of the suppressed 'Third World' directed against capitalist metropolis (Harrison, 1972) as well as of the 'rural guerrilla revolution'. Some West European countries endorsed the ideology of Eurocommunism, that is, a transition to socialism, which complied with all rules of democracy and renounced the dictatorship of the proletariat.

On the whole, the ideology gradually lost its momentum in the countries governed by communists, particularly in the Soviet bloc. A much greater significance was attached to this ideology by groups opposing the Soviet-style communism. In the late 1960s, some milieus of 'the new left' in Europe and America formulated the ideas of communist spontaneity, which were in opposition to capitalism and bureaucratic communism.

Many researchers have treated communist ideas mostly as one of the interpretations of Marxism. Popper (1945) wrote about the division of Marxists into radical (communist) and moderate (social democratic) wings. Walicki (1995) claimed that Leninism and Stalinism 'were dominant forms of the Marxist ideology of the twentieth century'. In his work on Marxism, Kolakowski (1978) handled the ideas of Leninism as one of the interpretations of Marxism, yet in some areas, he saw them as a departure from Marx's original views. An even clearer division of communist ideas from Marxism was drawn by Furet (1999). Although he did not deny that these ideas had originated from Marxism, Furet pointed to other sources of origin such as Russian populist ideas.

After the collapse of communist rule in European countries, communist ideology lost its popularity. The communist party in Russia associated its ideological tradition of Marxism–Leninism with very intense national and sometimes religious Orthodox elements (March, 2002). In China, officially the ideas of Marx, Lenin, and Mao are maintained but they do not play any important role in the daily propaganda of the Communist Party. Political leaders are speaking sometimes about these ideas, but with an interpretation to adapt them to 'socialism with Chinese characteristics' and they have eliminated the formula of class struggle as an obstacle to China's economic development (Chan, 2003). In China as in Vietnam and Cuba, the communist ideas are deeply influenced by the national emotions, and in the Asiatic countries, by a reference to the Confucian tradition. Nationalism and to some degree racism are present in the self-reliance ideology of the so-called Juche in North Korea (Myers, 2010).

There are some intellectuals who support the thesis concerning the durability of communist ideas and their importance for the prospective form of human relations, an alternative to capitalism. As a key question, they are giving attention to the creation of an egalitarian society. As a rule, this rhetoric avoids an appreciation of communist ideas preached in the 'real socialism' countries.

The Political Movement

When in 1903 the Russian Social Democracy split into two groups, the majority faction was called 'Bolsheviks' and the minority 'Mensheviks'. The Bolsheviks in 1912 formed a separate party, an organization of active revolutionaries. Although the principle of democratic centralism was introduced, in practice, the system was centralist and devoid of any traces of democracy. Furthermore, violence was endorsed as a fundamental means of political activity. All these features could be accounted for by the situation in Russia, where the parliamentary system was in its infancy and despotism ruled unabated.

The Bolsheviks came to power in Russia in 1917, whereas in 1918, they transformed themselves into a communist party. Since 1918, communist parties also emerged in other countries, mostly as a result of a split within socialist parties. In 1919, the Communist International (Comintern) was set up and it soon became centralized and dependent, as a matter of fact, on the Russian (or later Soviet) party. The terms 'communism' and 'bolshevism' were still used interchangeably and 'bolshevization' came to denote the process of following suit and imitating the example of the Russian party.

Communist political movements manifested themselves most intensively in Europe and China. They kept changing their political profiles, adopting to the then current situation on the international arena (e.g., under the pressure of the 1929–33 crisis), but, above all, complying with interests of the Soviet Union. In the 1930s, this compliance was linked with Stalin assuming the role of the undisputed leader of the international communist movement. Opposition groups were excluded from the movement. One of the few groupings that remained active were the proponents of Leo Trotsky, a prominent party leader expelled from the Soviet Union.

However, in the late 1930s, when faced with the threat of fascism, communist parties started to endorse the slogans of parliamentary democracy and entered into cooperation with socialists and even nonsocialist democratic parties (the 'People's Front'). When the Soviet Union entered into an agreement with Germany in 1939, communist parties all over the world declared their neutrality toward both parties in World War II.

This policy was subject to a drastic change following the 1941 German invasion of the Soviet Union. Only then did communist parties come to regard the struggle against fascism as their priority and fostered the idea of forming the National Front. The idea, however, was rarely put into practice for several reasons including dependence of communists on the Soviet Union (although Comintern was dissolved in 1943) and their aspirations to play a dominant role in the resistance movement.

When World War II was drawing to an end, communist parties took over power in the countries in which the Soviet army was present, as well as in Yugoslavia and Albania. In the countries occupied by the armies of the Western allies, communists frequently entered into ruling coalitions.

With the escalation of conflict between two political blocs and an upsurge of the 'Cold War', communist parties in the West went into opposition. The Soviet control over the international communist movement was strengthened anew in 1947 when the Information Bureau of Communist and Workers' Parties (Cominform) was established comprising the largest European parties. A year later, the first serious conflict between parties came to the fore, when the Yugoslav party was condemned by Cominform.

The victory of the communist party in China in 1949 (and later in Vietnam and Cuba) laid foundations for subsequent decentralization of the communist movement. The process of decentralization took place gradually following the death of Stalin in 1953, who 3 years later was accused of great atrocities. The escalation of the crisis in 1956 brought about the dissolution of Cominform, and resulted in reforms in Poland and a revolution in Hungary. The 1960s witnessed a conflict between the Soviet and the Chinese parties during which some other parties attempted to take advantage of the situation and gain independence.

Yet another crisis, triggered by the intervention of the Soviet bloc in Czechoslovakia, resulted in the adoption of Eurocommunist ideas by some West European parties in the 1970s. At the same time, small communist groupings emerged in the West drawing on the experiences (or rather their own visions of the experiences) of China, Vietnam, Cuba, or Yugoslavia. Further crises in the international communist movement were linked to the Polish conflicts of 1980–81. In the 1980s, both ruling and opposition communist parties showed symptoms of decay.

In the countries ruled by communists, a considerable number of works on the communist movement was published, yet their content was subject to control. The most important publications had even an official character (*The History of the Communist Party* 1938). Little changed in this respect in the communist historiography after the 'de-Stalinization', although the party ceased to stress the official character of publications, relying heavily on the censorship and monitoring of publications. These publications rarely contained reliable information, featuring mainly interpretations devoid of any critical approach and containing hagiographic accents.

Many publications were written by representatives of the communist opposition, who embraced the fundamentals of communism yet criticized the political line of Stalin and his successors, as it was in the case of the Trotskyists. Some of these texts resembled political commentaries and contained different information not included in the official and semiofficial communist literature. This trend also comprised publications based on extensive studies (e.g., Deutscher, 1949, 1954, 1959, 1963). Works by noncommunist authors fall into yet another category of literature relating to the history of the working-class movement. Although this literature contained fewer political commentaries, it demonstrated a strong socialist bias. From a left-wing socialist perspective, communism, in spite of all its shortcomings, was perceived as a proletariat movement close to socialist ideas and as a potential ally in the socialists' struggle against the bourgeoisie. Right-wing socialists, on the other hand, saw it as a hostile force striving to exert influence over the same social class.

In recent decades, however, the history of the workers' movement encompassing the history of the communist movement has become subject to more academic research.

Among authors who dealt with the communist movement, there were some who came from within the party ranks as well as those who broke free from its legacy. Others were emigrants from countries governed by communists, who drew on their life experience and language skills. One should also consider here expert publications of academic institutions that dealt with communism as a sideline political movement within a larger scope of interests relating to the so-called Sovietology.

After the collapse of communist systems in Europe, nearly all communist parties rejected their former ideological and organizational principles and transformed into socialist or social democratic parties. The existing European communist parties are rather weak, with some exceptions (in Russia, where the communists are the strongest opposition party, and also in Czech Republic). In the non-European countries with still ruling communist parties (China, Vietnam, North Korea, Cuba), they have a central role in the political system. In China, the communist party changed its social reference to workers and peasants and decided to open the party's ranks for the 'new classes' including the representatives of big business (Brady, 2008).

The Political and Socioeconomic System

Communists themselves are more prone to call it a socialist system. For the first time, such a system was introduced in Russia after 1917. Its principles were outlined by Lenin before the victory of the revolution, yet his work on this subject was published only when the Bolsheviks came to power (*Gosudarstwo i rewoljucija* 1918). Two principles were of particular significance: (1) the state has to resort to violence in the political and social life and (2) elements of a centralized bureaucracy, that is, record keeping and monitoring, play a key role in the organization of the economy.

In the Soviet political system, the leading role was assigned to the centralized communist monoparty devoid of any traces of democracy within its ranks. All organizations were subordinated to the party and headed by its members. Moreover, the party exercised control over all publications and mass media directly or through state departments (e.g., censorship). The state authorities at all levels reported to party organs. Initially, the state authorities were organized in a hierarchical structure of councils with some chosen representatives of lower level sitting on the councils of a higher level. Following the establishment of the Soviet Union in 1922, the party and state authorities were to function according to the principles of a federal state. The 1936 constitution provided for general elections at all tiers of power. In practice, however, soon after communists came to power, they introduced the principle of nominating from above, a principle that applied to both the party and state authorities. The approval of such nominations in public elections was a mere formality. This political system was adopted after World War II in all communist countries.

A considerable autonomy was enjoyed by the police, and above all by security services. They gained a strong position in the period of widespread repression in the Soviet Union (collectivization and 'big cleansing' in the 1930s) as well as in the countries within the Soviet sphere of influence (in the late 1940s and early 1950s) and in China (during the cultural revolution). Furthermore, security services attempted to exert a still greater political influence also in other periods.

Another pivotal element of the system was the army. In the Soviet Union, it owed its position to the role played in introducing the system and in World War II. Later, it was a key means supporting the rivalry between superpowers and

political blocs as well as the Soviet expansion in the countries of the Third World. Similarly, in China and Vietnam, the army was the cocreator of the system. In Poland, the army won a particular importance in the face of the imposition of martial law in 1981. On the other hand, party officials feared an excessive degree of independence of the army, which had far-reaching repercussions in the Soviet Union during repressions directed toward army officials in the 1930s.

In the Soviet bloc, which included European communist countries (with the exception of Yugoslavia since 1948 and Albania since the 1960s) as well as Mongolia and North Korea (for a couple of years), there were initially informal methods of control from Moscow. System monitoring was exercised through the Cominform and Soviet advisers or directives sent to high-ranking officials. Since 1956, methods of control were restricted and formalized by means of political and military structures of the Warsaw Pact, as well as structures of the Council for Mutual Economic Assistance (Comecon).

Gradually, the centralized systems began to crumble on international and state levels alike. Retaining its leading role, the USSR had to take into account more and more frequently the positions of the countries within the Soviet bloc. Several countries of the Soviet Block and China managed to hand down some power to regional levels. Yugoslavia carried out some transformations in its political system, introducing elements of a limited federalism and a local government.

Since 1953, several communist countries, particularly those belonging to the Soviet bloc, witnessed recurring political crises. They were triggered by people's rising democratic aspirations influenced by examples emanating from Western democracies, by the lack of respect for national sovereignty and, to a large extent, by a growing economic crisis and a low standard of living. Another precipitating factor was the disillusionment as to the application of communist ideas in practice.

Following the crisis in Czechoslovakia and the invasion of the country by the Soviet bloc, the Brezhnev doctrine was proclaimed (1968) asserting the right of the communist community to intervene when any of its members demonstrates 'antisocialist degeneration'. Communist officials adopted the formula of 'real socialism' as a form of the existing system hindered by historical limitations on the road to the socialist and communist future.

The economy in communist countries was subordinated to politics. Nationalization was implemented in all spheres of economic life. Although agriculture and, to some degree, trade and small production were formally owned by cooperatives, they were supervised by the party and state administration. There were only negligible relics of private ownership with the exception of Poland and Yugoslavia where agriculture remained in private hands.

Centralized state planning functioned on the basis of 5-year plans, the allocation of raw materials and means of investments, regulated prices, and rationing commodities for sale. A top priority was the needs of the state, which resulted often from an international policy. Particular emphasis was placed on the development of heavy industry and reservoirs of raw materials, neglecting other branches of production. In the face of constant shortages and a crippled economy, many goods intended for production and consumption were subject to different forms of rationing. The state's monopoly on foreign trade along with slow technological progress, a limited exports potential and, consequently, import deficit led to a form of economic autarchy.

Yugoslavia's economy demonstrated a slight divergence from this general pattern after the introduction of self-government in enterprises. Moreover, Yugoslavia fostered more extensively mechanisms of the market economy and managed to avoid autarchy. Nonetheless, it put a limit on foreign investments and failed to develop technological innovations.

Communist systems that were created almost exclusively in poorly developed or underdeveloped countries demonstrated initially a high rate of economic growth. The rapid industrialization combined with urban development was based on extensive factors such as a cheap labor force. However, as these factors were gradually exhausted, the growth rate began to decline and the standard of living stabilized at a low level. Among other factors that aggravated the crisis were the growing costs of the arms race and political rivalry between superpowers and blocs.

From the late 1950s, attempts were made to overcome the crisis. On the one hand, restraints of the arms race were accepted (the Helsinki Agreement of 1975, treaties on nonproliferation of nuclear and conventional weapons) and, on the other hand, planned economies were transformed slightly by introducing in them elements of a market economy and stimuli of a technological progress. In spite of a successful arms race reduction, the costs of armaments and political expansion still exceeded the economic potential of communist countries, whereas the introduction of elements of market economy generated strong resistance of the bureaucracy in the state and the party administration.

The 1980s saw not only a growing opposition against the political system but also an ever-stronger conviction of an upcoming defeat shared by communist officials. The need to conduct economic reforms called for a more extensive popular support, which was possible to achieve thanks to political reforms. Political reforms were pursued to a limited extent in the Soviet Union (economic *perestroika* accompanied by political *glasnost* – transparency) and in Poland (the 'roundtable' talks, an attempt to achieve a compromise with the opposition). Finally, the attempts to carry out limited reforms of the economic system were doomed to failure. Coupled with a disintegrated political system, they led to the collapse of communism over the years 1989–91.

In China, however, the authorities resorted to extreme means of repression against the opposition (the massacre at the Tian'anmen square, 1989). They were then successful in effecting its economic reforms encompassing devolution; privatization of agriculture, small- and medium-size industry, and trade; as well as the introduction of elements of market economy. The country managed to restore a fast rate of economic growth and development creating openings for foreign investments linked with the import of new technologies.

Communist researchers into the political and economic system concentrated their work mostly on its premises rather than on reality. A distinct character was noticeable only in the discussions before the 1930s, which touched upon the 'Asiatic

system of production'. These works tackled directly the prospects of building of the communist system in China, and, indirectly, they reflected some ideas on the political and economic system in Russia. Among basic characteristics of oriental societies, they featured a dominating role of the state in the economy and, consequently, the durability of absolutist and bureaucratic tendencies. This concept was raised in discussions in the 1920s by Karl Wittfogel. He broke away later from communism and came to regard the Soviet Union as a follower of Asian despotic systems.

The communist authors emphasized the class conditioning of the system. Many works presented a mystified picture of common interests of the state and society. They referred also to the notions of 'People's Democracy' or 'Socialist Democracy' (as a state of equal opportunities). Communist publications are of little academic value, yet sometimes they can communicate significant information.

In the noncommunist literature as a whole, there were prominent publications that dealt with communist systems within a wider historical framework. In particular, they referred to the connections between the history of Russia and of the Soviet Union. The principle of a historical continuity was propagated (Kucharzewski, 1948; Pipes, 1993; Besançon, 1980). This conception was often accompanied by a tendency to view communist systems as something superimposed by the USSR upon other countries.

The notion of totalitarianism was used initially in Italian fascism, later by researchers whose works dealt with German national socialism. In the wake of experiences and the atmosphere of the 'Cold War', communist systems were regarded by some researchers as one of the forms of totalitarianism (Arendt, 1951; Friedrich and Brzezinski, 1956). Arendt saw the roots of totalitarian systems above all in the current demise of human values and the crisis of principles underlying the existence of societies and individuals. Friedrich and Brzezinski focused mainly on the techniques of wielding power and the totalitarian syndrome.

Concrete studies of the system were heavily influenced by the concept of totalitarianism. The concept of communism as a form of totalitarian systems was undermined to some extent as a result of growing tendencies toward decentralization and curbing repression. Researchers started to concentrate more on the differences between communist countries as well as on the fact of how inconsistent their respective systems were (Brzezinski, 1960). Another approach to communism stipulated that the system was an attempt to implement utopia invented by doctrinaires (Heller and Niekricz, 1986; Malia, 1994). There were also other interpretations of the communist system according to which it was a peculiar way to modernization concerning in particular the Third World (Schurmann, 1966) or to a failed modernization in the Eastern part of Europe (Berend, 1996).

Some authors treated communism above all as a system of genocide. A different interpretation claimed that Stalinism was only a criminal distortion of the communist system. Political commentaries on the subject emerged before World War II. Afterward, scientific studies were preceded by documentary literature (Herling-Grudzinski, 1951; Solzhenitsyn, 1974). In the 1960s, Robert Conquest published monographs on various aspects of genocide in the Soviet Union. An international team has tried to apply a comprehensive approach to this problem (Courtois et al., 1997). The question of genocide pointed to a comparison between communism and Nazism and sometimes to the claiming of a communist priority, based on the timing and dimension of crimes.

After the collapse of communist rule in European countries and opening of archives, many books and articles about different questions related to the communist systems were published. They explained particular mechanisms and instruments of communist rule, as well as the different aspects of crises in the communist countries and causes for collapse of their regimes. One emphasized the moral, ideological, social, and political delegitimization of European communism (Okey, 2004).

At present, communist systems exist exclusively in the Far East and in Cuba. All of them introduced elements of a market economy, in a more consistent way and as an example to other Asiatic countries. These included not only China (Gittings, 2005; Guo, 2006) but also Vietnam, and within a limited scope Korea and Cuba. In all these countries, the communist party exercises an unlimited power, but in China and Vietnam, with much more respect for the needs and feelings of their population, and in the Democratic People's Republic of Korea (North Korea), with an extremely repressive system. China and Vietnam are rather open in their relations with the outside world, whereas the Korean system makes every endeavor to prevent its citizens from contacts with foreign lands.

Another difference concerns the form of dictatorship. All existing communist countries perceive the danger of an individual rule without the principle of succession. These changes have occurred in a contradictory way. China and Vietnam opted to a collective leadership. Korea and Cuba introduced a succession in the ruling family. Korea implemented a quasi-monarchical order of succession from father to son, but to a younger son instead of to the eldest.

Communitarianism

Abstract

The concept of communitarianism is developed by presenting the key elements and key theoreticians. The elements are a hermeneutic methodology, criticism of individualism, a concept of the good, the idea of community, and civic virtues. Among the key theoreticians, Charles Taylor, Michael Sandel, and Alasdair MacIntyre respond critically to the liberalism in the theory of John Rawls, emphasizing that it cannot explain loyalties to communities and the motivation to act morally. Michael Walzer relates common values and a shared idea of the just to common opinions in different Spheres of Justice that is directed against Rawlsian liberalism. Philip Selznick and Amitai Etzioni overcome the liberal-communitarian debate in pointing out that the development of common values presupposes freely consenting individuals. Robert Bellah points out the importance of civic engagement and value orientation for a Good Society. Etzioni criticizes on the one hand the negligence of the social context of individual integrity in liberal theory. On the other hand, he insists on internal democracy in communities as a criterion for the evaluation of value systems in order to avoid relativism and oppressive values. The concluding prediction is drawn that communitarian ideas will play a stable role in the self-reflection of modernizing societies.

Characteristic key elements of communitarian theory are the following five points: a hermeneutic methodology, criticism of what was called atomistic individualism, an Aristotelian concept of the good in opposition to rights, the renaissance of the idea of community, and a renewed insight into the relevant political function of civic virtues. Communities can be defined as webs of social relations that encompass shared meanings and shared values. Families may qualify as minicommunities, villages often are, although not necessarily. Communities need not be concentrated geographically, like the scientific community. Especially traditional communities are not necessarily places of virtue, but they can be oppressive, monolithic, and authoritarian. So a main problem for communitarian authors is to find overarching criteria to avoid accepting automatically any commonality of shared self-understanding as a good community (Etzioni, 1998, p. XIV).

In the 1980s, a group of political theoreticians – Charles Taylor, Michael Sandel, and Michael Walzer – challenged what they perceived as excessive individualism by the insight that individuality is based and dependent on social context. The radical liberal idea of an 'unencumbered self' was criticized as self-refuting, because it fostered antisocial behavior with the tendency to undermine its own social preconditions.

The academic and public impact of communitarianism has come about for two reasons. It seemed to give a theoretical answer to the most important political philosophy of the time, for example, the individualist liberalism of the renewed contract theory of John Rawls and others. The second reason is even more important: politically, communitarianism was a critical reaction against the 'liberalism of greed' of the Thatcher and Reagan years, so it became attractive to the New Democrats and New Labor as a rhetoric to win back the votes of the middle classes. In the early 1990s, Etzioni and others decided to take these ideas from the campus to the larger society. They founded the journal *The Responsive Community* and tried to establish communitarian ideas as a recognized third way of political thinking between liberalism and conservatism. Different from former communitarian ideas in the tradition of Ferdinand Tönnies (*Gemeinschaft und Gesellschaft*), Robert Nisbet, and Martin Buber, the new communitarians pointed out that a responsive community tries to avoid any authoritarianism and oppressiveness against the individual. The old communitarians privileged social bonds and traditional small communities over the individual. Communities in their definition were villages, small cities, some religious sects, and tribes. Asian communitarianism overemphasizes social harmony. The new American line of communitarian thinking concentrated much more on the question of balance between individual rights and social responsibilities. Individual autonomy and the common good are to be brought into a new equilibrium. It tried to add a sense of the social and communal preconditions of social integration to rights-centered liberalism and liberal neutrality.

The anthropologic key concept of modern communitarian thinking is Taylor's idea of humans as self-interpreting animals (Taylor, 1985b). Modern identity is based on inescapable frameworks of interpretation, which provides the background language for strong evaluations of right and wrong, good and evil, higher and lower. The quality of this framework is decisive for the quality of the society. Sandel radicalized this idea and transformed it into an argument against Rawlsian liberalism: the original position as a metaphor for justice, where nobody knows about his or her later social position before a decision is taken, is not only practically impossible (Rawls would agree), but also theoretically undesirable, because this conception of justice would lead to a world inhabited by morally neutral people without any character. Persons without loyalties to their family, their community, nation, or people are in Sandel's view persons without character. MacIntyre emphasized the missing foundation of liberal theories of justice. Even more, modern concepts cannot provide any motivation to act morally, because they are not based on fully responsible persons, but only on character masks such as the manager, the therapist, or the Kierkegaardian aesthete.

This anti-Rawlsian criticism was not conclusive, because his principles of justice were not meant to shape the whole person, but only their behavior in the political realm. Even more, Sandel did not take into account the possibility of a person

taking a distant stand from their community. So the foundations of Sandel's (and, as traditional virtues are concerned, MacIntyre's) criticism seemed to be rooted in old-fashioned communitarianism without the reflection of the fact that modern American society can be interpreted as the social basis for some kind of responsive individualism. Both Sandel and MacIntyre were uncomfortable with the label 'communitarian,' but their ideas belong to the present discussion of the concept.

A quite different kind of communitarian theory was developed by Walzer, who is also uncomfortable with the term, but refers to the same set of methods and ideas. In his *Spheres of Justice. A Defense of Pluralism and Equality* (1983) his social criticism and his ideas for reform lean on the hermeneutic interpretation of commonly shared values. The well-known tension between shared values and social practice is sufficient to legitimize social reform. Walzer's method differs on the one side from liberal Kantian or Rawlsian social constructionism, and on the other from conservative belief in the objectivity of traditional values (social ontology). Justice is only possible if it takes into account the differentiation of spheres. Different modes of distribution have to be applied concerning membership and citizenship, political power, security and welfare, money, office, education, recognition, kinship, and love. There is no general theory of justice, but a special justice for each of these spheres. What is considered as just depends on commonly shared and publicly discussed opinions about the criteria of justice.

The liberal-communitarian debate of the 1980s and early 1990s seems to be over at present. Those who decided to stick to the label 'communitarians' now call themselves liberal communitarians or communitarian liberals, such as Selznick (1992) and Etzioni (1996). The central idea is that, in a modern society, common values and virtues can only be developed by freely consenting individuals, not by the state or by pressure from religious movements of the fundamentalist denomination.

Selznick's 'communitarian liberalism' draws on the social philosophy of John Dewey. Morality is always community based. Character and integrity are relevant for the function of large organizations, including the state. A proper understanding of communities implies diversity and pluralism as well as social integration. It has to have a strong sense of a common good. Thus, Selznick combines sociological functionalism with the value-based traditions of American pragmatism. His interpretation of the term 'covenant' means a self-defining commitment, and an act of faith and resolve by the individual. It is prepolitical, foundational, and consensual. Liberal neutrality misses this aspect, and is based only on institutions for the purpose of social integration. Conservatism, on the other hand, tries to overload institutional processes with value orientations. The communitarian third way tries to restore values and virtues as functional prerequisites of the civil society.

Bellah et al. (1991) try to describe the state of American society and to make statements about its long-term viability through insights into its mores and the climate of opinion. They lean on Alexis de Tocqueville's *Democracy in America* (1835), which seems to be a key text for most communitarians. The results of the study are communicated in terms of eloquent sadness: the self-destruction of the liberation promises of modernity and the retreat from public engagement into the private sphere of the family and friends is stated by many of the interviews. Most of them articulated a profound yearning for the idealized small town, which can be interpreted as a yearning for meaning and coherence, for commitment, and community. The social ecology is not intact if there are no communal answers to the extreme fragmentation of modern everyday life. The ubiquitous language of individualism, in which American self-understanding normally is articulated, limits the ways in which people think and cuts off the opportunity of a broader orientation (once called 'civic virtues,' Bellah et al., 1985, p. 290). Because of their option for more substantive ethical identities and more active political participation Bellah and coworkers were labeled as communitarians. They preferred to describe their position in a slightly different way to avoid the risk of being misunderstood, privileging only small face-to-face groups such as families, congregations, and neighborhoods, and of being opposed to the state and all the other larger structures that dominate life at the start of the twenty-first century. They insist that freedoms and a Good Society depend on institutions, and they are critical that many individualistic Americans have trouble understanding and accepting social and political institutions (Bellah et al., 1991).

Etzioni's main criticism of liberal political theory is the negligence of the social preconditions that enable individuals to maintain their psychological integrity, civility, and ability to reason. On the other hand, he distances himself from those communitarians who hold that as long as a community has agreed on a set of values, these are the ultimate criteria as to what is morally appropriate (Etzioni, 1995, p. 17). The central problem is to establish criteria for the evaluation of the internal value system of different communities. The question is: how to avoid perspectivism and relativism, and to develop criteria to rule out authoritarian and oppressive community values. In the first place, internal democracy of the community is the criterion. But additional criteria are needed, because a majority in a specific community might violate individual and minority rights. The second criterion is a substantial process of consensus building within a community. Beyond any particular community, the values of a society as a whole are a framework within a higher order of legitimacy; that is, the application of the Constitution, especially the Bill of Rights. The third level is the cross-societal moral dialogues, in which the societal values have to be legitimized against others. The fourth criterion is the global community. But even the global community might act oppressively, as it did when women were excluded from voting worldwide until the end of World War I. So the last resort for the dissenting individual is the clearly communicable self-evidence of some core values.

All these criteria have in common that they are based on moral dialogues of different reach, not on ontological values or on artificially constructed value systems. The communitarian approach is the support of concrete societal and, if necessary, cross-cultural moral dialogues. Of course, they have to be limited to a set of core values (Etzioni, 1996, p. 237). Through these reflections Etzioni tries to overcome the restriction of traditional communitarian thinking to limited communities and to bring into discussion the notion of a global community. These are questions the worldwide discussion of communitarian ideas has made inevitable. Communitarian approaches

have to solve the question: Which community? What kind of community? Who belongs and who does not? This will be important especially for further discussions on the problem of multiculturalism (cf Taylor et al., 1992).

The discomfort with the label 'communitarian' seems to be a general characteristic of many authors in this field, with the exception of Etzioni. Communitarianism seems to be a permanent, accompanying phenomenon to liberalism, but can hardly stand on its own. The traditional social structures of community orientation have been dissolved by the processes of modernization, individualization, and fragmentation. Attempts to restore or invent dense forms of social integration as an answer to modernity such as communism, fascism (*Volksgemeinschaft*), or some forms of Islamic fundamentalism are discredited because of their atrocities and their contempt for individual rights. Thus, in modern, technology-based service economies, communitarianism is only acceptable as a reflexive admonition to care more about the common good, but not as a coherent and mobilizing social ideology. So the prediction follows that communitarian ideas in a moderate form of social self-reflection and social integration programs will be a permanent subdominant melody in the chorus of further modernizing societies, because it meets a fundamental human demand for social integration on a theoretical level.

The latest developments in communitarian political theory are marked by the publication of Michael Sandel's assessment of the moral limits of markets (Sandel, 2012), a criticism of the growing dominance of economic rationality over the other spheres of society. The core argument is in line with the communitarian tradition: Principles of Justice have to be developed from the respective pluralist contexts, not from only one narrow concept of rationality. Charles Taylor (2007) has presented a comprehensive diagnosis of our 'Secular Age' and of the conditions of religion and belief after secularization. Taylor's approach to the secular age offers a new turn in the sociology of religion. His concept of secularization is based on the idea that the United States as a whole society is secularized. It is no longer a society where it was virtually impossible not to believe in God to a society, where faith is one human possibility among others. His communitarian perspective concentrates on the context, the societal background of possible religious experiences. In this new form, the secularization thesis can resist challenges from authors like José Casanova, who argue that secularization only happened in Europe, but not in the United States and in Latin America.

Abstract

'Communitarianism' is the name adopted by a group of American and British thinkers in late twentieth century to describe their shared sociological and philosophical concerns, and the ideas developed by them and their intellectual precursors in earlier times to address these concerns. One of its key themes is that society would be ultimately deficient and unstable, unless people learn to cultivate shared values and pursue them in cooperation with each other. Its significance is best understood as an evolving social philosophy that responds critically to threats to the development of inclusive community life.

What Is Communitarianism?

In the 1840s, the term 'communitarian' came into usage to describe the approach to community building through cooperative education and organization, championed by the British reformist, Robert Owen, and his followers on both sides of the Atlantic. In the 1980s, the same term was used by academic commentators as a generic label for an otherwise diverse group of thinkers (Alasdair MacIntyre, Charles Taylor, Michael Sandel, and Michael Walzer) who had one thing in common – they all penned criticisms of John Rawls' liberal philosophy because it treated people as unencumbered selves without reference to their relationships to their communities.

It was in the 1990s that a group of social and political theorists in Britain and America formally adopted 'communitarian' as the name for their shared philosophical outlook. Through the writings and collaborations of these thinkers, who included Philip Selznick, Robert Bellah, Jonathan Boswell, Amitai Etzioni, and Henry Tam, a body of work emerged to elucidate what communitarianism is about, provide a framework for understanding its intellectual heritage dating back to fifth century BC, and point to future challenges in the twenty-first century, particularly in relation to the twin threats of local community life being fragmented and global social development failing to generate sufficient shared values and solidarity.

Aristotle's insightful correction of Plato's reduction of all human beings into narrow categories assigning them in a single monolithic state is arguably one of the earliest examples of communitarian criticism. By pointing out that people are irreducibly social beings who are attached to a range of communal associations, Aristotle rejected the Platonic assumption that morally or intellectually people can be coherently defined in abstract terms without due reference to the relationships they have or seek in actual communities.

The disagreement between the two Greek philosophers, however, pales in comparison with the disputes that erupted in China from fifth century down to third century BC. The fierce contest between the traditionalist Confucians, the communitarian Mohists, and other rival schools of thought brought into sharp relief the dividing lines between conflicting visions of how society should be organized. Against those who just wanted to preserve rigid traditional hierarchies, those who would prefer to ignore all hierarchies and ties, and those who sought to impose new hierarchies at will, the communitarian followers of the philosopher, Mo Tze (*c*.479–399 BC), advocated the development of communities based on mutual values. They had to defend not only their doctrines but also their lives when their commitment to oppose aggressive wars put them repeatedly at odds with lords and princelings seeking to make territorial gains by force.

The Mohist and Owenite concerns with displacing oppressive social structures, not with any kind of free-for-all individualism, but with a deliberative and experimental reconstruction of community life based on the development of mutually respected values, point to philosophical continuities that ran through the late nineteenth/early twentieth century communitarian ideas of Émile Durkheim, L.T. Hobhouse, Jane Addams, and John Dewey, down to the contemporary advocates of communitarianism.

The key challenge facing communitarians in the twenty-first century is the resurgence of the 'self'-centred conception of human interactions. Academic relativism and popular culture converge on detaching the 'self' from any objective set of values with which it can be morally judged and socially restrained. The 'self' may be that of unaccountable political leader, a fundamentalist extremist, a corporate magnate, or simply an individual who cares nothing for the effects of his or her actions on others.

Communitarians reject both the relativist neutrality of supposing individual 'selves' should be left alone to act as they wish and authoritarian injunctions to impose the rigid order of hierarchical communities. Instead they put forward arguments and proposals to enable ordinary citizens and those in leadership positions to find ways to build and sustain a more inclusive form of community life, with the help of shared learning, deliberative dialogues, and participatory forms of collective decision making.

Although advocates for traditionalist hierarchical communities are sometimes labeled 'communitarians,' this is a term those advocates have never adopted, and their ideas have consistently been criticized by the writers who actually refer to themselves as communitarians. In this article, the term 'communitarian' is therefore applied only to the ideas that are philosophical antecedents of, intellectually complementary to, or directly expressed in, the works by thinkers who have used the term 'communitarian' to describe their own stance.

The Emergence of Communitarian Thinking and Its Critics

The core themes of communitarian debates first emerged in ancient China, during the late 'Spring–Autumn' and early 'Warring States' periods (500–250 BC), when rival social philosophers contested how stable and prosperous community life could be engendered against a backdrop of growing social fragmentation and armed conflicts. Four distinct positions were articulated. Their interrelationships provide a better illustration of what are in dispute than the more commonly invoked communitarian-liberal polarization.

The first position was formulated by Confucius (551–479 BC) and staunchly defended by his followers. In essence, it maintains that society functions best when it has a firm hierarchical structure, and everyone accepts the traditional role that has been assigned to them without seeking to usurp someone else's position. Its favored tool of socialization is the inculcation of rites and customs, with which people are routinely reminded that they ought to do what is expected of them.

Against this position, the Taoists advocated a romantic form of anarchic individualism. The writings attributed to Lao Tze (*c*.550–450 BC) suggested that the ruler should do as little as possible, leaving people to live in small communities in accordance with their own wishes. Chuang Tze (*c*.369–286 BC) went even further in proposing that individuals should withdraw from conventional ties altogether and follow whatever mode of behavior that might take their fancy. The Taoists believe that such liberated individuals would have a much better life without the pressures exerted on them by rigid social structures.

The Mohists (named after the founder of their school of thought, Mo Tze, *c*.479–399 BC) challenged both the hierarchical traditionalist thinking of the Confucians, and the anarchic individualism of the Taoists. The communitarian alternative they put forward consisted of three key elements. First, members of communities are more likely to attain an improved quality of life if they are prepared to support others as they would like to be supported themselves. Second, what kind of mutual support would be most effective should not be determined by reference to customs or revered texts alone, but with the help of a combination of historical records, contemporary observation, and future experimentation. Third, communities must devise ways of acting together in order to advance the kind of mutual support backed by a critical review of the evidence.

While the Confucians attacked the communitarian Mohists for their refusal to respect the total sanctity of customs, the Taoists frowned upon their determination to organize for collective action, the Legalists (flourished *c*.third-century BC) attacked all their rivals on the basis that they assumed human beings could be expected to serve what those in the ruling position might deem to be the greater good without being made to do so by forceful commands. The fourth position rejects moral traditions, critical reasoning, and benign individualism as unrealistic drivers for social goals set by a ruling elite. Instead, it posits the need for strict laws backed by stringent sanctions to direct social behavior.

This four-way contest provides a framework for understanding the roots of communitarianism and for mapping its core disagreement with rival social theories on how communities should be organized. These divisions have resurfaced throughout history in China and other parts of the world, and they represent underlying tensions in the diverse approaches for resolving disagreement within as well as between sovereign states.

Cooperative Ethos and Communitarian Social Experiments

Although the Enlightenment is often characterized as a movement for individualism, it contains important strands of communitarian thinking. As Peter Gay (1973) pointed out, it was no accident that the most quoted moral philosopher amongst pro-Enlightenment writers in the eighteenth century was Cicero who advocated the pursuit of the common good through civic solidarity and informed deliberations. It was Robert Owen (1771–1858), who synthesized a range of Enlightenment ideas into a cogent social philosophy which set a new mission for education; inspired the cooperative movement, and promoted social experiments that came to be known by the mid-nineteenth century as 'communitarian' (the earliest recorded use of the term dates back to 1841).

What Owen set out in *A New View of Society*, essays on the principle of the formation of human character (1991, originally published 1813/14), was bold in its analysis and radical in its prescription. Owen maintained that people's lives could be substantially improved if they interacted with one another in mutually supportive communities, rather than carrying on with exploitative arrangements, which benefited a powerful few at the expense of the majority. He further argued that experimental alternatives could be developed to test out how social arrangements could be reformed irrespective of what traditional beliefs might be invoked to defend the status quo. Most importantly, he claimed that education held the key to giving people the skills, confidence, and will to bring about new social arrangements.

Owen helped set up cooperative enterprise where workers and their families were treated with respect, given educational support, and empowered to share in the profits generated. His example inspired the widespread development of cooperatives, which gave their members an equal say in the running of their workplace communities.

Owenites in the United Kingdom and those who emigrated to the United States set up diverse communitarian experiments to enable people to take greater control of their lives, not as isolated individuals, but as fellow members of shared communities. What was sociologically significant about these experiments was that they opened the door to a new way to explore forms of human association. Instead of abstract models with their theoretical pros and cons, the Owenites pioneered the development and adaptation of community life through education and practical organization. As J.F.C. Harrison (2010) explained, while those early experiments produced a mix of successes and failures, they pointed later generations to the possibility of critical community development.

The Relationship between Liberalism and Communitarianism

Although in the 1980s there was a common trend in focusing on the debates between John Rawls and his communitarian

critics (e.g., Charles Taylor, Michael Sandel, and Michael Walzer) as a contest between liberalism and communitarianism, a close reading of these critics would reveal that they rejected any suggestion that they were putting forward an alternative social philosophy in the form of 'communitarianism' to displace liberalism as such. What they were interested in was to pick out particular weaknesses in liberal thinking, and explained why a more robust understanding of human relationships, in the context of what would constitute healthy and coherent community life, was necessary to supplement those liberal insights that were in fact valid. As such they echoed the intellectual debates that began a century earlier and which characterized the reorientation of liberal ideas in late nineteenth/early twentieth century.

Individualist liberalism had by the 1890s leaned toward an increasingly laissez faire outlook that would have heartened the most radical Taoists, if not for the fact that instead of an overbearing state, there were now powerful factory owners, merchants and bankers who were imposing the social arrangements they favored on people who, on their own, had no chance of making any alterations to those often oppressive arrangements.

Against this transformation of liberalism into a doctrine that privileged the commercial elite, turn-of-the-century thinkers such as Émile Durkheim, L.T. Hobhouse, Jane Addams, and John Dewey led a counter-movement in rethinking what a society that is both liberal and communitarian should be like.

For these thinkers, liberal concerns with freeing people from arbitrary intervention were not to be rejected wholesale for a communitarian alternative form of life. On the contrary, they believed those concerns needed to be properly addressed by recognizing that individuals would only develop freely as social beings if they were able to learn to live with and support each other as members of shared communities. Drawing on communitarian experiments in education, cooperative enterprise, and democratic collective action, they began to reorientate liberal thinking toward a more proactive commitment to community development.

Important studies have shown that communitarian thought grew in the context of augmenting liberalism, not in seeking to undermine it. Anyone wanting to know more about the symbiotic relationship between communitarian and liberal ideas in these thinkers should consult the works on Durkheim by Mark S. Cladis (1992); on L.T. Hobhouse and what came to be known as *New Liberalism* by Stephan Collini (1979); and on Dewey by Alan Ryan (1995), especially the section 'The Communitarian Turn' in Chapter 9. Re-acquaintance with their arguments to bolster liberalism with communitarian insights should go some way to displacing the misleading dichotomy of 'liberalism versus communitarianism' that became fashionable for a time in late twentieth century.

The Focus of Modern Communitarianism

In the 1990s, the long tradition of sociological insights and public advocacy relating to the critical development of community life outlined in the previous sections was further developed and applied to contemporary social problems when a group of American and British thinkers formally adopted the 'communitarian' name to describe this philosophy.

In the United States, Amitai Etzioni brought together a wide range of scholars and public figures, including William A. Galston, Philip Selznick, Robert Bellah, and Thomas Spragens Jr., under The Responsive Communitarian Platform: Rights and Responsibilities, a joint manifesto summarizing the core concerns of the group; produced the journal, The Responsive Community; and set up the Institute of Communitarian Policy Studies (http://icps.gwu.edu/).

In the United Kingdom, Henry Tam founded the Communitarian Forum with academics and civic leaders such as Tony Skillen, Chris Ormell, Lord Phillips of Sudbury (President, Citizenship Foundation), and Sheila Bloom (Chief Executive, Institute of Global Ethics, United Kingdom); devised a communitarian 'Working with Communities' program that was recognized with a national award by Prime Minister Tony Blair; and set up the Civil Renewal Unit for the UK Government in 2003 to run the 7-year nationwide 'Together We Can' campaign (http://www.hbtam.blogspot.co.uk/2013/06/find-our-more-about-together-we-can.html).

A good introduction to the core views of the modern communitarians can be found in the following key texts: Jonathan Boswell's (1990) *Community and the Economy*; Philip Selznick's (1992) *The Moral Commonwealth*; Amita Etzioni's (1993) *The Spirit of Community* and (1998) *The Essential Communitarian Reader* (edited collection); and Henry Tam's (1998) *Communitarianism*, and (2001a) *Progressive Politics in the Global Age* (edited collection).

These communitarian writers want to draw attention to five underlying problems engendered by the resurgence of a 'self'-centred social and political outlook since the 1980s. The growing emphasis on the individual self as owing nothing to anyone but one's own 'self' was exacerbating the corrosive effects of relentless marketization and the deterioration of social bonds. For communitarians, these problems would continue to worsen unless a better understanding of what would make for healthy relationships in the multiple layers of community life was attained to inform attempts at finding long-term solutions.

Of the five problems, the first and foremost is the failure to give adequate attention to both rights and responsibilities. If we only defend individuals' rights to claim what they in isolation seek to claim as their entitlement, and neglect to press people to recognize and fulfill responsibilities they owe others, those rights may become hollow in any case. As societies become ever more socioeconomically polarized, the need to find a proper balance between rights and responsibilities becomes even more urgent when those who have the most insist on their rights to do what they want with their wealth, while those with the least are repeatedly told to take responsibility for their own plight with little help from others.

The second problem is the masking of indifference as the face of neutrality. The imposition of values, especially when it would in effect exploit some to gratify others, is dubious at best, and repugnant at worst. But the rejection of objectionable values does not entail the rejection of all values. Radical relativism gives succor to irresponsible individuals who would like to pretend that everything they do is morally neutral. By reconnecting people to the attitudinal and behavioral expectations they actually have on others, communitarians believe the fabric of common values can be weaved together again.

Third, there is the problem of the neglect of communities by both state and market. In the nineteenth century, liberal constraints on the state were widely called for and applied, but that led to businesses becoming so powerful that they could dictate terms to people as workers and consumers. In the first half of the twentieth century, the state expanded to deal with the problems caused or neglected by the market. But throughout, the capacity of ordinary people to get involved, have a say, or exert some real influence over their lives was diminished. Both government institutions and businesses need to face up to the urgent need to rethink how they are to enable communities to play their part in a more balanced and inclusive society.

The fourth problem concerns the unfortunate severance between a sense of universal respect and a commitment to more local, communal attachments. In a globalized world, people increasingly look to their families, neighborhoods, and national borders for a sense of belonging and security. But at the same time, they need to adapt more than ever to interactions beyond settled boundaries. In place of the dichotomy of either a bland universalism or a blinkered localism, communitarians seek to help build the solidarity for a worldwide community of diverse communities.

Finally, human beings in the modern world need to be reconceptualized as people whose potential for a fulfilling life is developed and realized as members of overlapping communities. The tendency to see them as nothing more than cogs in a corporate machine, utility-maximizing consumers, or free-floating atoms indifferent to their proximity to others must be challenged.

The Key Communitarian Principles

In order to tackle the aforementioned problems, communitarians not only highlight the contradictions and distortions in the misguided conceptions of human relationship in contemporary society, they also put forward ideas for new models of interaction and power structure that would enable their participants to reach a more nuanced understanding to guide the future development of their social, economic, and political arrangements.

There are broadly three communitarian principles that are central to shaping appropriate models for human interaction. First, the principle of cooperative enquiry requires anyone making an assertion to be judged with reference to the extent to which informed participants deliberating under conditions of thoughtful and uncoerced exchanges would concur. Any provisional consensus reached by one group of individuals must in turn be open to possible revisions subject to examinations carried out with input from other groups. The ultimate strength of any truth claim rests with the likelihood of that claim surviving the critical deliberations of ever expanding circles of enquirers.

Second, the principle of mutual responsibility requires all members of any community to take responsibility for enabling each other to pursue those values which stand up to the test of reciprocity. What an individual may value cannot expect to command the respect from others if its pursuit is incompatible with the realization of goals valued by others. The range of mutual responsibilities may expand over time to cover, for example, direct and indirect care for dependents, help to those who would otherwise be neglected, safeguards for verifiable evidence and coherent reasoning, and cultivation of personal abilities not inimical to those of others. Omission to support, as well as action to harm, would be deemed a breach of the responsibility owed to each other.

Third, the principle of citizen participation requires that all those affected by any given power structure are to be able to participate as equal citizens in determining how the power in question is to be exercised. All those subject to potentially binding commands should be entitled to learn about, review, and determine how to reform decision-making processes. This applies to not only government institutions, but also businesses, schools, and community organizations. It follows that power relations should not retain structural or cultural barriers which hold people back from accessing information, putting forward their suggestions, questioning proposals, or sharing in decision-making processes.

The application of these principles to devising and evaluating modes of human interaction will help to show up barriers and identify specific improvements that should enable the people involved to relate to each other as members of communities with shared values. In practice, however, both established institutions and the mind-set of individuals will need to be changed if the communitarian principles are to be realized.

Communitarianism and Social Change: Key Questions

Communitarians want to transform communities so that they move closer to what community life should be like. At the most basic level, a community is no more than a group of people who have something in common which brings them and keeps them together. What is in common could be a geographical location, a historical identity, the fear of a common enemy, a place of worship, a shared interest, a common employer, or a bond that has grown out of solidarity against similar prejudices and discrimination.

At any given time, however, there are already social and institutional arrangements in place. Where these are entrenched and yet ill-disposed to embrace the improvements sought, communitarians face the problem their critics routinely present to them: how can they bring about social change without disrupting, and possibly undermining, prevailing community structures?

There are at least four lines of criticism derived from this problem. First, there is the suggestion that communitarian aspiration for social change is hemmed in by the limits set by many hierarchical communities. This applies to modern corporations as much as to traditional communities. Instead of complacently leaving those in charge to reform from within, communitarians have put forward substantial social, economic, and political reforms to open up debates on what changes ought to be considered (see, e.g., the works of Boswell, Etzioni, Derber, and Tam). Communities that have become accustomed to neglecting some of their members may well be reluctant to change, and that is where strong advocacy, subtle persuasion, and vivid presentation have their role to play in altering mind-sets and building alliances for social transformation.

Second, communitarians are often accused of demanding homogeneity as a precondition for effective community life. It is claimed that they want to secure social cohesion at the expense of cultural pluralism because they believe that the rejection of a common set of values and practices would lead to instability and conflicts. But the emphasis on the importance of common values and practices is not inherently incompatible with individual autonomy.

The distinction Durkheim and Hobhouse drew between mechanical and organic solidarity helps to explain precisely that whereas the narrow values which underpin mechanical solidarity demand total homogeneity, organic solidarity offers the opportunity for individuals to develop themselves and attain a stronger sense of social cohesion at the same time. Values grow out of an expanding mutual understanding between people. The fear of 'foreign' or 'alien' is often most pronounced in those areas where people are most isolated from others with different lifestyles and cultures. The community bonds in cosmopolitan cities show that people can have a strong sense of shared belonging and at the same time have attachments to diverse interests and customs within the overarching framework of a set of inclusive common values.

The third type of criticism concerns the issues of power and dominance in established communities. Advocates for women, gays, disabled people, minority ethnic groups, are rightly troubled by the sense of righteous behavior carried out by the members of certain communities. In those communities, some people define their identity in a disturbingly large part in terms of the superiority they allow themselves to feel toward those who are traditionally discriminated against.

The sociological starting point adopted by communitarians would maintain that there are different forms of community life. To develop those which are most likely to promote the widest opportunities for individual growth without fragmenting communal links into a state of indifference or even conflicts, we need to break down barriers to equitable power distribution so that through open communications and co-operation we can identify appropriate reform strategies. It follows that existing communities of family, neighborhood, and nation should be evaluated critically in relation to the key communitarian principles. The more they contain oppressive relations and practices which demand the unquestioned obedience of those in subordinate positions, the more they need to be exposed as authoritarian and subject to radical transformation.

The fourth and final area of criticism concerns the exclusivity of communities. This objection concerns the compatibility between strong community identity and the inclusive ideal of a community of communities. Miller (1990) and others have claimed that the two are incompatible because communities must have a high degree of exclusivity if they are to provide their members with a real sense of belonging.

From a communitarian point of view, community identity does not rest on exclusive allegiance. We can, and many of us do, feel a real sense of belonging toward a multiplicity of communities, our neighborhoods, towns, counties, regions, nations, clubs, unions, professional bodies, work teams, interest-based societies, lobbying groups, etc. Many of these enable their members to be involved in major decisions which affect their lives. Furthermore, these communities do associate with each other both horizontally and vertically. For example, the voluntary groups of a town coming together to form an umbrella group for the town; clubs across Europe forming a continental association; local businesses joining with regional businesses to set up a business support organization; and national and regional politicians working together on common interest issues. Some of these links are not strong, but others create their own communities where the sense of identity and belonging is as important as that within one of the constituent communities, and the nation state is only one of these communities.

People's attachment to a web of communities means that exclusivity is often an imagined desire rather than an actual barrier to a fulfilling community life. In reality, the task of developing healthy interactions within and between a multiplicity of communities is one becoming more urgent as the process of globalization takes out the option of communities existing in complete isolation from one another. As different communities impact more and more on each other, they will only be able to flourish if they learn to relate to each other by cultivating a set of common values and practices to which they will give their support. The alternative is a collusion course between rival communities, which will undermine the well-being of all.

Communitarianism, Education, and Community-Based Learning

Communitarians rely on deliberative education and reasoned persuasion to win over hearts and minds in changing communities. Like the Mohists, while they recognize that traditions and customs may have a role to play in ordering society, they insist that these must be supplemented, and where appropriate corrected, by facts we learn from experience and ideas that can be tested out through social experimentation.

Education therefore has a central role in communitarian philosophy. There are three aspects that merit particular attention. First, the education of children raises the question of what and how they are to be taught. Since from a communitarian perspective, dogmas and prejudices cannot be defended as just another set of customary beliefs or group values, the contents of education can be contested and arguments put forward to support teaching that upholds the communitarian principles. Schools need to move forward in terms of their structures and teaching methodologies so that pupils, teachers, and parents can function as partners in raising understanding. Fielding and Moss (2010) provides an example of how a more democratic and communitarian ethos can be developed in schools. In England, the cooperative movement in the 2010s began to give systematic support to the development of cooperative schools, which formally integrate the communitarian values of the movement into the running of each school. Outside the school, there is the issue of how the socioeconomic status of parents may affect the access their children have to effective education. Where individuals and schools cannot overcome these problems, the state at the local or national level would need to help parents and children – from support to enable them to have enough to eat or travel to school, to the provision of advice to parents and facilities for after-school care where necessary.

Second, there is the educative influence beyond teaching institutions for young people. Work-based learning, adult education, and media output generally can shape people's understanding and attitudes to a large degree. Not only is it necessary for schools to prepare for what other sources of influence may be at work on their pupils' minds, society also needs to be aware what people are led to think and feel after they have left school. Just as what parents or schools teach their children cannot be ringfenced as their private business that has nothing to do with the wider society, the activities of media, trainers, lifelong learning providers, research institutions, advertising and public relations agencies, all have social impact which cannot be shielded from critical scrutiny. Liberal safeguards against arbitrary censorship are not to be seen in this context as insurmountable barrier to public intervention, but as providing a reliable framework to counter the promotion of falsehoods and prejudices. Furthermore, the common good is not to be enhanced necessarily just by negative constraints, and it is likely that public support in the form of investment and coordination can considerably strengthen the quality and dissemination of research and information.

Finally, there is the need to improve education in citizenship and democratic collaboration. Communitarians have written about how the disposition and skills toward interacting with others with a mix of shared values and conflicting views should be cultivated. One of the most comprehensive initiatives to develop such an educational approach across all social spheres – in schools, community groups, local government, businesses, public policies – was taken forward by the British Government when it set up the Civil Renewal Unit in 2003 with the communitarian, Henry Tam, as its head. The initiative, under the title of 'Together We Can,' enabled neighborhoods to learn in partnership with public and private bodies how to improve their common well-being. It supported Civic Pioneer local authorities to help local residents and groups as well as their own staff to deepen their understanding of how more effective democratic decision making can be achieved. It helped academic institutions, community activists, and public service providers to develop Take Part projects to facilitate active citizenship learning in a wide range of communities. It also funded regional Community Empowerment Partnerships in all parts of England to bring together diverse groups and organizations to share ideas on how best to spread learning on what came to be known as 'cooperative problem-solving.'

Tam's (2013) paper on 'Cooperative Problem-Solving and Education' and the web resource generated by the 'Together We Can' program demonstrate how communitarian ideas on social transformation can be taken forward by coordinated efforts to educate citizens and the diverse communities to which they belong in applying cooperation and conflict resolution approaches in cultivating shared values, so as to attain better forms of community life.

Communitarians

Matteo Bortolini, Università di Padova, Padova, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Communitarians' is the collective label used to identify a number of Anglo-American scholars who in the 1980s proposed a heterogeneous set of philosophical and sociological arguments as a critique of rights-based and universalistic versions of liberalism. After the philosophical debate faded in the mid-1990s, the label has been used to identify the members of an intellectual-political movement founded by Amitai Etzioni. The first section presents the main ideas of the four theorists who were widely considered as representative of communitarianism – Michael Sandel, Alasdair MacIntyre, Charles Taylor, and Michael Walzer – and explains their explicit rejection of the 'communitarian' label. The second section focuses on Etzioni's carefully crafted intellectual-political movement and investigates its imaginative relationship with the philosophical debate on liberalism and community.

Introduction

During the 1980s and the 1990s the label 'communitarians' was used to indicate a heterogeneous aggregate of intellectuals who shared a broad and articulated appreciation of community-centered philosophical arguments and political proposals. Thanks to its hermeneutical and narrative methodology, socially embedded conception of human beings, and the importance it ascribed to a collectively held conception of the good life, communitarianism was often associated to both republicanism and radical conceptions of democracy as the main alternative to the deontological and individualistic versions of liberalism championed by thinkers as John Rawls, Ronald Dworkin, and Robert Nozick. As the philosophical debate over liberalism and community waned in the mid-1990s, the label was used to define the members of an intellectual-political movement – the 'responsive communitarians' – founded by Amitai Etzioni in 1991. Lists of communitarian philosophers usually include Michael Sandel, Alasdair MacIntyre, Charles Taylor, and Michael Walzer, while Etzioni, Philip Selznick, and Robert Bellah are counted among the most representative communitarian sociologists.

Any reconstruction of the collective biography of the communitarians should take two apparent paradoxes into account. First, the four philosophers who were deemed as the major 'communitarians' have rejected such a label – ironically, one may even point to this denial as their only common trait. Second, while their ideas figure prominently in the literature associated with Etzioni's movement, they were not personally involved with the latter and some doubt could be cast about their substantial influence on the movement's 'Responsive Communitarian Platform.' In fact, the label 'communitarians' was projected from without on a diverse group of scholars to define them, first, in their relationship to another school of thought, mainstream procedural liberalism, and, second, as the intellectual forerunners of an organized intellectual-political movement. Most retrospective accounts have recognized and ignored both the uneasiness shown by Sandel, MacIntyre, Taylor, and Walzer toward the communitarian label and the lack of personal links with the responsive communitarians, and have discussed their work from a highly synthetic and abstract point of view – the only strategy that allows to group the four philosophers as 'communitarians.' In fact, as they presented arguments located on a host of different epistemic levels (methodological questions about the premises and the articulation of moral reasoning, ontological conceptions of the relationship between the self and society, and normative and advocacy-oriented positions), thinkers who might share the same ground on one level often parted ways on the others. In order to take the self-identification of the four scholars into account, the label 'communitarians' would have to be dropped in favor of other definitions – such as 'republican,' 'civic-humanist,' or, in Walzer's case, 'social democrat.' At that point, however, the scope of the story would have to be extended to include all non-individualistic versions of modern political theory and, with them, a diverse array of theorists.

What follows presents the collective biography of the 'communitarians' from a historical-sociological point of view which accounts for the emergence of the communitarian label by looking at late twentieth-century Anglo-American political and social theory as relational intellectual fields in which the position of each scholar was defined by the positions occupied, and the views promoted, by other actors. The first section supplements the summary of the main ideas of the four putative communitarian theorists – Sandel, MacIntyre, Taylor, and Walzer – with an investigation of their network of intellectual relationships aimed at explaining their differences and their response to the process which labeled them as 'communitarians.' The second section is dedicated to Etzioni's translation of the communitarian label from the philosophical debate to a carefully crafted intellectual-political movement of which no one of the four philosophers was a member. As it happens with any translation, this processes involved creative shifts in content, scope, and tone which are both intellectually and sociologically interesting.

'Communitarians' vs Liberals

Michael Sandel's *Liberalism and the Limits of Justice* (1982), the book which is widely considered as the debut of modern-day communitarianism, emerged from its author's experience as a student at Oxford in the late 1970s, where the thought of Aristotle, Kant, and Hegel was filtered by the philosophical

insights of Charles Taylor, the Canadian philosopher who occupied the Chichele chair of social and political theory, and Alan Montefiore, a British philosopher conversant with both the analytic and the continental traditions. The intense exchanges within a network which also included Stuart Hampshire, Ronald Dworkin, Leszek Kołakowski, Michael Oakeshott, and Sheldon Wolin, led Sandel (b. 1953) to develop a critique of what he saw as the thread joining apparently diverse versions of liberalism, the privilege accorded to 'the right' over 'the good' – the idea that a pluralist society is best arranged when it is governed by principles of justice that do not presuppose any particular conception of the good.

Sandel's criticism focused on the most influential contemporary rendition of Kantian-inspired liberalism – *A Theory of Justice*, the groundbreaking treatise published in 1971 by the Harvard philosopher, John Rawls, as a critique of Utilitarianism. Using an array of analytical arguments and thought experiments – among which the idea of an 'original position' where the actual distribution of natural talents, preferences, and social positions is hidden beyond a 'veil of ignorance' in order to reach a universalistic agreement on some basic principles of justice – Rawls had defined an articulated conception of 'justice as fairness' meant to replace the principle of utility as the main theoretical device for assessing the moral worth of the distribution of social and economic advantages in a democratic society. Besides receiving the critiques of major Utilitarians such as Richard M. Hare, Rawls had been attacked from a libertarian point of view by fellow Harvardian Robert Nozick, who grounded his case against redistributive justice on the absolute right of personal self-ownership (*Anarchy, State, and Utopia*, 1974).

Liberalism and the Limits of Justice criticized *A Theory of Justice* from the opposite pole of the philosophical spectrum: according to Sandel, Rawls's Kantian 'unencumbered' self, prior to its ends and independent from them, was too thin to justify both its adhesion to the principles of justice (the right) and its choice of ends (the good). In contrast, Sandel proposed an 'encumbered' idea of the self, whose identity was already constituted by a plurality of pre-existing communal narratives shared by different groupings of concrete human beings (family, city, tribe, class, nation, people); the encumbered self presupposed a constitutive understanding of the community which was at odds with the instrumental and sentimental conceptions of communal life acknowledged in *A Theory of Justice*.

Sandel first used the adjective 'communitarian' in the introduction of *Liberalism and Its Critics* (1984), a reader in which he collected, among the others, selections from Taylor, MacIntyre, Walzer, Oakeshott, Peter L. Berger, and Hannah Arendt. Sandel explicitly contrasted Utilitarianism and Kantian liberalism with the 'growing challenge' of 'communitarian critics' inspired by Aristotle, Hegel, and civic republicanism. In 1985, the American philosopher Amy Gutmann published an influential article, 'Communitarian Critics of Liberalism,' where Sandel, MacIntyre, Taylor, Walzer, and Roberto Unger were labeled as 'new communitarians.' Gutmann's intent was clearly polemical. Whereas 'old' – that is, Marxist – communitarians strived for equality and collective property ownership, modern communitarians favored 'traditions and established identities.' Gutmann defended Rawls against what she saw as an attack to individual rights and the very idea of justice, and criticized Sandel's suggestion of reviving the civic republican stream implicit in the American tradition on the ground that it would bring back majoritarianism and, eventually, 'Salem.'

A flow of articles – including well-known papers by Will Kymlicka, John Wallach, and Christopher Lasch – and special issues of journals quickly followed Gutmann's lead. The debate was mostly fed by liberals, who defended the deontological version of universalism from what they perceived as untimely, misguided, or even authoritarian critiques. The 'communitarian' label was often used in a dismissive and negative way which effectively, albeit not always openly, referred to Ferdinand Tönnies's discredited inclination for traditional *Gemeinschaft* over modern *Gesellschaft*. In fact, a rapid survey of the intellectual biographies of the alleged communitarians – all belonging to an older generation than Sandel's – reveals a broad overlapping of networks and interests (respectively, the British New Left and participatory democracy), as well as different scopes, arguments, and self-identifications – a heterogeneity that most of the commentators acknowledged but decided not to emphasize.

Educated at McGill University in Montreal and at Oxford under the supervision of Hampshire and Isaiah Berlin, Charles Taylor (b. 1931) developed an early interest in the thought of European thinkers such as Maurice Merleau-Ponty and Emmanuel Mounier, as well as a militant political activism in the British New Left (together with Stuart Hall, Gabriel Pearson, and Ralph Samuel, he was a founder of *Universities and Left Review*) and in the Canadian New Democratic Party. His first book, *The Explanation of Behaviour* (1964), focused on the continuing relevance of teleological explanations of human (and animal) agency, while his 1967 essay, 'Neutrality in Political Science,' argued for the convergence of empirical inquiry and normative theory within the framework of a wider hermeneutical view of the social and human sciences. In his book *Hegel* (1975), Taylor asserted from a non-Hegelian standpoint the significance of Hegel's work for the recurring modern problem of situating 'subjectivity by relating it to our life as embodied and social beings, without reducing it to a function of objectified nature.'

In the liberal-communitarian debate, Taylor was mostly cited for his 1979 essay, 'Atomism,' in which he attacked the Hobbes-Locke tradition of political theory and the priority it granted to individual rights in the justification of political action and institutions. Taylor argued that the primacy of individual rights was implicitly based on an anthropology of individual self-sufficiency, to which he opposed a theory of 'the social nature of man' according to which the very identity of independent individuals demands a 'social matrix' – a set of practices which recognized the individual's autonomy and his right to participate in deliberation about public action. In his conclusion, he underlined that any 'free individual' should be committed to sustaining the society which rendered his identity possible, reaffirming his principled support to the very idea of individual rights.

Born in New York City in 1935, Michael Walzer studied at Brandeis University with Lewis Coser and Irving Howe, whose journal, *Dissent*, published his first political articles and reportages in the late 1950s. A political activist in the civil rights movement and an affiliate with British New Left circles, Walzer studied in Cambridge, UK, with Geoffrey Elton and at Harvard

under the guidance of Samuel Beer, Barrington Moore, Jr., and Judith Shklar. In the mid-1960s, Walzer joined the Society for Ethical and Legal Philosophy – along with Thomas Nagel, Dworkin, Rawls, and Nozick – a company which would prove crucial for the development of his ideas on justice, community, and individual rights. In his early publications – e.g., *Obligations* (1970) and *Just and Unjust Wars* (1977) – he employed a contextualist method in which political theory was used to frame the study of historical processes, and historical cases were utilized to clarify theoretical arguments.

The focus of liberal critics of 'communitarianism' was Walzer's *Spheres of Justice* (1983), a book grown in a constant dialogue with Nozick (with whom Walzer taught a course on 'Capitalism and Socialism' in 1970–71), Gutmann, and Taylor, as well as with Clifford Geertz, Albert Hirschman, and Judith Jarvis Thomson. The book put forward a complex vision of distributive justice grounded in a 'thick' interpretive understanding of material and immaterial goods as deeply intertwined with the story of both communities and personal identities. Each social good, according to Walzer, constituted an autonomous distributive sphere within which only certain standards and rules were appropriate. Consequently, the biggest obstacle toward justice was the 'dominance' of one good over other goods. *Spheres of Justice* advanced a conception of 'complex equality' where arrangements of the different spheres would be defended by the political community, which should take the form of a participatory 'decentralized democratic socialism.' Walzer's work was from the very beginning closer to liberalism than Aristotelianism. While justice was always rooted in the particular understandings that constituted a 'community' as a shared way of life, the community he was speaking of was a democratic, differentiated, and ultimately liberal Western society.

In Alasdair MacIntyre's *After Virtue* (1981) the political focus that characterized, albeit in different manners, the works of Sandel, Taylor, and Walzer was subordinated to an analysis of the moral malaises of modernity. As a student in London, Manchester, and Oxford in the 1940s and 1950s, Scottish born MacIntyre (b. 1929) made his debut with a book in which he traced the intellectual relationships between Marxism and Christian theology (*Marxism: An Introduction*, 1953). Originally a member of the same New Left circles to which both Taylor and Walzer belonged, MacIntyre shifted his political allegiance to the Trotskyist *International Socialism* group around 1960. The publication of *A Short History of Ethics* (1966) was a step away from Marxism, a divorce that was consumed with the second edition of his first book, now titled *Marxism and Christianity* (1968). In 1969, MacIntyre moved to America and participated in the so-called 'Hegel Craze' of the mid-1970s editing an important collection of essays, *Hegel* (1972), to which Taylor contributed along with Walter Kaufmann and Shlomo Avineri.

In *After Virtue*, MacIntyre criticized the 'grave moral disorder' of contemporary society, and traced it back to the failure of the 'Enlightenment project.' Since morality is always rooted in a particular way of life, the universalistic quest of modernity could only fail in an unsettable clash of vocabularies, *genres*, and disembodied ideas – in this sense, Nietzsche had correctly understood that the Enlightenment would finally bring up the dessication of moral rationality and the advent of emotivism and nihilism. As an alternative, MacIntyre called for a neo-Aristotelian teleological ethic based on a composite understanding of human virtues. MacIntyre's conclusions restated that the contrast between modern and classical moral philosophy and suggested that the creation of a new kind of secluded community aimed at preserving the true moral life from the attack of modernity's 'barbarians.'

After Virtue undoubtedly resounded with both Taylor's and Sandel's works for its conception of morality as a set of norms which human actors 'find' as soon as they undertake their quest for the good life. At the same time, the differences were striking. Whereas Sandel's book was a thorough analysis of Rawls's *A Theory of Justice*, MacIntyre's critique of contemporary liberalism only occupied a short chapter at the end of a long history of Western ethics. Moreover, whereas none of the other alleged 'communitarians' opposed the general framework of contemporary political institutions, MacIntyre wrote that modern politics 'simply had to be rejected.' These substantial differences did not prevent liberal critics to consider MacIntyre as one of 'the communitarians' and to attribute an impoverished summary of some of his more radical positions to Sandel, Taylor, and Walzer.

Given these premises, it is no wonder that in the mid-1980s the four philosophers started to explicitly position themselves vis-à-vis the 'liberal-communitarian' debate – paradoxically, in distancing himself from 'communitarianism' each took for granted that such a position did exist and that at least some of the others would identify themselves with it. In 1989, Taylor published an article titled 'Cross-Purposes: The Liberal-Communitarian Debate,' in which he characteristically distinguished two sets of issues (ontological and advocacy-related) and pleaded for a more complex vision of the debate that would dissolve the two labels, for ontological questions (holism versus atomism) might influence, but never determine, the choice between political positions (individualistic versus collectivistic). In distinguishing the two 'teams' Taylor did not enroll himself neither among the communitarians (Sandel, MacIntyre, Walzer) nor among the liberals (Rawls, Dworkin, Nagel, Scanlon); rather, he filed his own work under the 'civic humanist' and republican tradition of 'holistic individualism.'

In a 1990 essay, Walzer saw 'the communitarian critique of liberalism' as a recurring feature of modern political thought and distinguished two versions of it. According to the first, liberal political theory accurately depicted liberal societies as aggregates of isolated individuals – Walzer ascribed this view to neo-Marxists, neo-conservatives, and neo-classical republicans, among which he included Sandel and MacIntyre. The second version of the communitarian critique maintained, on the contrary, that liberalism misrepresented social life. According to the 'vulgar idealism' of the authors of *Habits of the Heart* (of which more later), by negating the commonal texture of social life, the rhetoric of liberalism put modern society at risk. Walzer acknowledged the fragmented nature of modern society, but argued for the existence of a 'liberal tradition' as the foundation of a modern society. At the same time, he advanced the need to teach 'liberal selves' to consider themselves as the living embodiment of liberal values, a public goal that could only be furthered by a 'deliberately nonneutral' State – an idea that Walzer attributed to John Dewey. Siding with the liberals, Walzer closed his essay with two final critiques to 'communitarians': first, civic republicanism was too focused on the

political sphere to be viable; and second, since political theory regards the relations between constituted selves, the whole discussion on the self was purposeless.

Although they had been associated with communitarianism even by Taylor and Walzer, neither MacIntyre nor Sandel would accept the label. In the 'Postscript to the Second Edition' of *After Virtue* (1984), MacIntyre did not take on anti-'communitarian' critiques and only wrote about on the three relationships on which his forthcoming volume, *Whose Justice? Which Rationality?* (1988), was built: that between philosophy and history, that between his conception of virtues and ancient wisdom, and that between his work and Biblical theology. MacIntyre explicitly declared his distance from 'communitarianism' at various times and places – finally in the introduction of the 2007 edition of *After Virtue*. As for Sandel, soon after the publication of his book he wrote 'The Procedural Republic and the Unencumbered Self' (1984), a widely reprinted essay in which he summarized his thesis about the need for a deeper understanding of the communal foundations of liberalism, but somehow started to shift from analytical arguments to historical narrative. His 1994 book, *Democracy's Discontent*, presented a detailed, theoretically informed account of the emergence of the 'procedural republic,' defined as the practical embodiment of liberal neutralist ideals, from the Independence up to the mid-1990s. Ultimately, in the preface of the second edition of *Liberalism and the Limits of Justice* (1998), tellingly titled 'The Limits of Communitarianism,' Sandel declared 'some unease' with the 'communitarian' label and restated his case for a perfectionist and republican understanding of politics and law where rights rested on a substantive moral judgment of the ends they advanced, thus explicitly distinguishing his position from both liberal neutralism and communitarian majoritarianism.

The 'Responsive Community Platform' and Communitarianism

In the early 1990s, the debate between liberals and communitarians thrived and assumed such a central and attractive position that even those scholars belonging to other schools of thought – e.g., feminists or neo-Marxists – were almost compelled to take a position toward it, both in the United States and abroad. Will Kymlicka (1989), Robert Booth Fowler (1991), Stephen Mulhall and Adam Swift (1992), Stephen Holmes (1993), and Derek Phillips (1993) all dedicated detailed monographs to the critique of communitarianism, whereas readings and anthologies were edited by David Rasmussen (1990), Shlomo Avineri and Avner De-Shalit (1992), and Cornelius Delaney (1994). All these works took for granted that a small group of cultural objects – *Liberalism and the Limits of Justice*, *After Virtue*, *Spheres of Justice*, and some of Taylor's essays – constituted the nucleus of the 'communitarian critique of liberalism.' Since the dynamic of the production and exchange of new arguments and texts depended less on Sandel, MacIntyre, Taylor, and Walzer's intentions than on the ongoing structuration of the field of moral and political philosophy, the self-understanding of the four theorists, and their subsequent work, could do little to stop the process. Daniel A. Bell's *Communitarianism and Its Critics* (1993) was one of the few books which patently defended the communitarian approach. In the introduction, Bell suggested that the philosophies of Sandel, MacIntyre, Taylor, and Walzer might function as a sound scholarly basis for the intellectual and political project outlined in Amitai Etzioni's 'Responsive Communitarian Platform,' irrespective of the fact (which Bell recognized in a footnote) that the four philosophers had never declared to be 'communitarians' and were personally unrelated to Etzioni's movement.

German-born Etzioni (b. 1929) was a well-known sociologist, who had hitherto been extraneous to the philosophical debate. He studied with Martin Buber and Shmuel Eisenstadt in Jerusalem in the 1950s, before enrolling at the University of California at Berkeley, where he got his PhD in sociology under Seymour M. Lipset's guidance. In 1958, Etzioni was hired by Columbia University, where he spent most of his academic career writing on organizational sociology (*A Comparative Analysis of Complex Organizations*, 1961) and intervening as a public intellectual on topics as diverse as the prospects of a nuclear war, Project Apollo, the war in Vietnam, and biotechnologies (*The Hard Way to Peace*, 1962; *The Moondoggle*, 1964; *Genetic Fix*, 1973). An advocate of reindustrialization – his ideas for 'rebuilding America' were spelled in *An Immodest Agenda* (1983) – in the late 1970s Etzioni briefly served as an advisor to President Jimmy Carter. His 1990 book, *The Moral Dimension*, criticized neoclassical economics from a 'socio-economic' view according to which economic actors and processes should be understood as embedded in social relations and cultural values.

Profoundly concerned about the excesses of Reaganian individualism and the refusal to debate moral issues on the part of progressive liberals, in early 1990 Etzioni, now at George Washington University, and William Galston, a professor of public affairs at the University of Maryland, gathered a small number of scholars to discuss the creation of an intellectual and political agenda. The group included, among the others, Philip Selznick, a sociologist who had enthusiastically embraced the 'communitarian' label in his 1987 article 'The Idea of a Communitarian Morality'; political theorists Benjamin Barber, James Fishkin, Jane Mansbridge, and Thomas Spragens; and William Sullivan, a philosopher who had co-authored with Berkeley sociologist Robert Bellah and three young colleagues *Habits of the Heart* (1985), a brilliant critique of the excesses of American individualism that was commonly regarded as one of the landmarks of sociological communitarianism. It was decided that the group would take its name from the title of a short essay Etzioni had published in 1987, 'The Responsive Community (I & We),' and would elaborate a far-reaching moral and political program, which Etzioni drafted with the help of Galston and Mary Ann Glendon, the Harvard Law School professor who had just published *Rights Talk* (1991).

The 'Responsive Communitarian Platform: Rights and Responsibilities' was published in 1991 and was endorsed by a diverse group of intellectuals, politicians, and activists, among which were Bellah, Harvey Cox, Albert Hirschman, Richard John Neuhaus, Lester Thurow, Francis Fukuyama, David Riesman, Orlando Patterson, and Adlai Stevenson. The Platform advanced a deeply embedded vision of the human individual and stressed the need of balancing rights and responsibilities on both the side of the individual and that of

the many different communities to which each citizen of a pluralist, democratic society belongs. In order to strengthen the communitarian fabric of American society, the movement called for a stronger civil society founded on 'moral education and character formation,' and emphasized the role of both families and schools in rendering citizens sensitive to their duties toward each other and the wider political community. Etzioni stressed the importance of balanced, 'average' two parent families and refused the identification between communitarianism and majority rule, calling instead for a more participative and stronger democracy. The Platform also contained policy suggestions on domestic disarmament, parental leaves from the workplace, national and local service, and the reduction of campaign financing. In calling for more solidarity and less individualism, more grassroots initiatives and less bureaucracy, Etzioni's agenda looked for a third way between conservatism and liberalism that was nonetheless rooted in a modern understanding of politics.

These themes were restated and reworked in Etzioni's *The Spirit of Community* (1993) and *The New Golden Rule* (1996), two books aimed at reaching a wider, non-academic public. Along with Galston, Fishkin, and Glendon, Etzioni also launched *The Responsive Community*, a quarterly journal dedicated to communitarian concerns. The journal's editorial board included public intellectuals such as Martha Nussbaum, Jean Elshtain, Nathan Glazer, and Daniel Yankelovich. As Galston took a job as the President's deputy assistant for domestic policy, the Clinton administration sponsored a host of communitarian initiatives, among which were the annual White House Conferences on Character Building. In the 1990s, communitarianism and its main spokesperson, Etzioni, were widely praised in the United Kingdom, where Tony Blair subscribed to the Platform, and Germany, where Etzioni was able to gain support from social democrat, green, and conservative leaders.

The use of the noun 'communitarians' to refer to the members of Etzioni's movement suggested a fundamental continuity between the philosophical debate of the 1980s and the political movement of the 1990s, a relationship that was often taken for granted in critical literature, popular understanding, and encyclopedia entries. From the point of view of intellectual networks, the four 'original' communitarians maintained very different stances toward the movement. While Walzer and Sandel remained indifferent, in 1991 MacIntyre sent a letter to *The Responsive Community* in which he unquestionably rejected the label 'communitarian' on philosophical and political grounds. Even if he never endorsed the Platform, Taylor expressed his sympathy for the movement and in 1994 became a member of the editorial board of *The Responsive Community*, contributing four articles before the journal shut down in 2004 (Sandel contributed one article, Walzer none). In 1995 Etzioni edited an anthology, *New Communitarian Thinking*, aimed at establishing communitarianism as a robust social and political theory in its own right; interestingly enough, the reader included three essays by Walzer, Taylor, and Sandel, which did not belong to the key works of the liberals/communitarians debate.

In reclaiming the very label that no one of the four 'communitarian' philosophers wanted for himself, Etzioni succeeded in branding a viable intellectual-political position which creatively combined the community-oriented plea for the duties and the responsibilities of an educated citizenry with the liberal stress on individual rights. As an alternative to the cleavage between conservatives and liberals typical of contemporary American politics, Etzioni's communitarianism revamped a discourse of commonality and embeddedness that echoed with the communitarian *Zeitgeist* of the post-Reaganian era without embracing either the radical conclusions of Alasdair MacIntyre or the social democratic ideals of Michael Walzer. For this and other reasons, the continuity between the diverse works of Sandel, Walzer, Taylor, and MacIntyre, and Etzioni's sociological understanding of the relationship between the individual and society should not be taken for granted and deserves a more thorough examination from both an intellectual and a historical point of view.

Communities and Crime

Abstract

Crime clusters in communities, most often in those communities plagued by a host of other social problems, such as poverty, joblessness, and family dissolution. In the mid-1980s, many scholars dismissed the relevance of community characteristics on crime; today their study is a veritable cottage industry within criminology. This article (1) provides a synthesis of both the classical and contemporary research on the mechanisms through which community-level processes influence crime, (2) examines the areas of future exploration of these mechanisms, and (3) highlights research on how these mechanisms influence crime in specific types of communities.

Theoretical Understandings of Crime and Community

The classic and influential work of Shaw and McKay (1942) provides the foundation for contemporary work examining characteristics of communities and crime. According to Shaw and McKay, community distress created social disorganization, defined as the disruption of primary relationships, the weakening of norms, and the erosion of shared culture. Shaw and McKay's original formulation of the social disorganization theoretical model, presented in Figure 1, would have only included three cells as follows: the exogenous variable, concentrated disadvantage; the dependent variable, community crime rates; and an undifferentiated intervening variable, social disorganization (represented by the large gray box in Figure 1 labeled 'processes of social disorganization'). This foundational version of the theory proposed that concentrated disadvantage (e.g., poverty, joblessness, social isolation, residential instability, etc.) led to social disorganization, which in turn determined community differences in crime rates. While concentrated disadvantage could have had a direct effect on crime by generating instrumental crime, the primary mechanism through which disadvantage affected crime was through the conditions conducive to social disorganization, simply defined as the inability of a community to instill in its members a shared sense of cultural values and effectively sanction those who deviate from those values (Krohn, 1985; Sampson and Groves, 1989).

Up until the late 1980s, social disorganization theory was largely discounted for failing to articulate the precise mechanisms through which concentrated disadvantage influenced crime. In large part this was an unfair critique (Bursik, 1988). Early social disorganization theory was clear in its premise that concentrated disadvantage eroded shared norms and limited the capacity of neighborhood networks to socialize and sanction their members. However, Shaw and McKay's original version of the theory allowed for little variation in the

Figure 1 Heuristic model of social disorganization theory.

relationship between concentrated disadvantage and social disorganization. For the most part, the theory took a deficits-based approach (Almgren, 2005). If a community exhibited concentrated disadvantage, it would also exhibit social disorganization. The original theory did little to explain how some communities plagued by concentrated disadvantage were able to remain organized, efficacious places while others were not. Over the past 20 years, contemporary social disorganization research has addressed this weakness by exploring the role of a variety of factors in mediating the effects of concentrated disadvantage on crime (Sampson et al., 2002). These factors include institutional support mechanisms, social networks, a sense of community, and collective efficacy (represented by the dark gray cells embedded in the larger light gray box in **Figure 1**).

The contemporary social disorganization model (represented by the full model in **Figure 1**) defines communities as systems of interrelated networks. The role of a community network, according to social disorganization theory, is to maintain itself through the continued socialization of its members, including, but not limited to, the application of negative sanctions to deviant members. The maintenance of this system can be undermined by social disorganization manifested at the community level as weak social networks, limited participation in local organizations, and little social control. As the antithesis of social disorganization, each aspect of social organization (networks, organizations, and control) forms the social fabric of a community (Kasarda and Janowitz, 1974). This social fabric structures communities in the following ways. First, both formal social networks (e.g., school, church) and informal social networks (e.g., extended family, neighbors) enable community members to recognize nonmembers and thereby guard property of members against crime perpetrated by nonmembers. More importantly, these social networks sanction members for actions that are criminal (Krohn, 1985). Second, participation in local organizations serves to instill community solidarity through the support of those institutions that are the organizational base through which community members work toward common goals (Kornhauser, 1978). Finally, social disorganization is manifested as the inability of a community to exert either positive or negative social control on its members. In past research, this has been understood most often in terms of supervising juveniles in order to prevent delinquency.

Social Networks within Communities

The capacity of a community to exert control over its residents exists if for no other reason than neighbors know one another and interact on a regular basis (Sampson and Groves, 1989). Community networks, by definition place-based networks, control crime by reinforcing shared values; censuring criminal behavior, especially juvenile delinquency; and increasing communal guardianship of property (Bursik and Grasmick, 1993). However, neighborhood social networks need not be strong to exert social control. Building on the idea of the strength of weak ties (Granovetter, 1973), Bellair (1997) demonstrates that broad, loosely woven social networks often operate as well as narrow, tightly woven ones. Even in loosely organized networks, people look out for one another, acting as 'eyes on the street' in protecting each other's persons and property. Conversely, networks can be dense, but overwhelmed by the effects of concentrated disadvantage leaving residents with little control over their local environment (Wilson, 1996). Moreover, not all types of social networks lessen crime. Criminal networks, such as gangs and drug networks, generate significant crime and offset more efficacious networks (Venkatesh, 2000). Likewise, nonreciprocal, draining networks, can increase social isolation for those who eschew the burden of such relationships (Kleit, 2010).

Institutional Support Mechanisms

Social networks serve as the linchpin of the social disorganization model (Morenoff et al., 2001). However, social networks are 'necessary, but not sufficient' mechanisms of social control (Kubrin and Weitzer, 2003: 377). They work to affect crime through three key intervening mechanisms as follows: Institutional support, sense of community, and collective efficacy (see **Figure 1**). At what is often termed the parochial level (Bursik and Grasmick, 1993), social control is generated in a formalized way through engagement in local organizations (e.g., block watches and resident associations) and institutions (e.g., churches and schools). Local organizations and institutions link individuals and their social networks to broader economic and political structures (Peterson et al., 2000). Some serve as the physical places within which social networks operate. Others can provide employment thereby linking individuals to conventional values (Wilson, 1996). Moreover, neighborhoods can develop the capacity to generate social control externally at the public level by securing goods and services from larger political entities, such as police departments and city governments (Bursik and Grasmick, 1993). Differences in aggregate social capital across neighborhoods operate in this region of the model. Access to institutional support mechanisms, especially those embedded in the broader urban political economy, is determined in large part by the aggregate social capital a community can leverage (Putnam, 2005). All social capital is not, however, the same. Putnam (2005) differentiates between bonding, bridging, and linking capital. Bonding social capital exists within homogenous communities and serves to reinforce shared norms and values among like people. Bridging social capital pulls together people who may be sociodemographically diverse, but are hierarchically equivalent, creating horizontal networks that can effectively share information and leverage diverse resources for political lobbying. Finally, linking social capital connects people vertically across socioeconomic hierarchies, tying those with direct access to social and economic resources to those without. Bridging social capital may link the interests of higher and lower income community members, thereby increasing aggregate social capital and decreasing crime. In this context, higher income residents provide the social, economic, and political leverage that will lead to institutional involvement and that this connection to institutional support mechanisms will secure crime prevention for all of the community residents, regardless of socioeconomic background (Curley, 2010). This may not occur in all socioeconomically heterogeneous communities, however. Higher income residents may choose not to interact within their proximate environment and rather

invest their institutional resources outside the neighborhood (e.g., going to churches, sending their children to schools, and frequenting businesses outside the neighborhood) (Tach, 2009). And where institutional investments emerge within mixed-income neighborhoods, they may not benefit low-income residents. Low-income residents may be left out of major decision making in a community; once enforced, decisions on zoning, crime control, and other policies may work to ostracize, isolate, or criminalize lower income residents. This process can create institutions that support some community members and disenfranchise others, thereby undermining social organization.

Collective Sense of Community

While local institutions and social networks may serve as indicators of social organization in a community, research has also examined the role of less instrumental indicators of social organization. A sense of community can emanate not just from the people (social networks) and places (local institutions) in that community, but also from the feeling of belonging that individuals possess. Having a sense of community gives residents a social psychological incentive to work together to solve common problems (Chavis and Wandersman, 1990). Research on juvenile delinquency finds that youth from neighborhoods with a strong sense of community engage in more prosocial behaviors and suggests that emotional ties to place are the best indicators of whether someone is truly a part of a community (Cantillon, 2006). This shared sense of community can also encompass the idea of a neighborhood subculture. Kubrin and Weitzer (2003) point out that while subculture was a key aspect of Shaw and McKay's (1942) understanding of community organization, this focus has been omitted from recent research.

Social networks also facilitate the creation of a strong sense of community. Sense of community can be physical (connected to the place) or relational (connected to the people) (McMillan and Chavis, 1986). Emotional ties to a certain place and/or its people give community members a psychological incentive to solve problem together, separate from the incentives of resource attainment or the solidification of shared values (Chavis and Wandersman, 1990). Ties to community can develop place-based subcultures that are beneficial in attenuating the effects of concentrated disadvantage, even in very poor communities. Living in such communities necessitates the sharing of resources, often creating a shared place-based subculture within which members of the community view sharing of responsibilities as a basic survival mechanism – for example, residents helping with childcare so single mothers can get to work. This shared place-based subculture can also create the perception of shared security despite the realities of crime (i.e., the feeling that 'everyone has your back') (Clampett-Lundquist, 2010). Mutual trust and feelings of connectedness among neighbors can provide intangible benefits. These benefits include social support and information sharing (e.g., regarding childcare, jobs, and other resources), as well as informal social controls (e.g., discouraging crime or other undesirable behaviors such as smoking or alcohol use among youths, drunkenness, littering, and graffiti) (Sampson et al., 2002). The social support in this context can create feelings of safety because community members know and look out for their neighbors. Place-based subcultures are not necessarily beneficial, however. Some research suggests that ties to community may be based on a shared oppositional subculture that emphasizes street-code conditioning, negating actions like contacting the police and curtailing crime, especially among youth (Kubrin and Weitzer, 2003).

The Role of Collective Efficacy

At the forefront of the resurgence of social disorganization theory in the late twentieth century was the concept of collective efficacy. Collective efficacy is simply the aggregate capacity of a community to work toward common goals (Sampson et al., 1997). Socially organized communities, in other words those with a sense of community, intact networks, and vibrant community institutions, have a greater capacity for collective efficacy than disorganized communities. While sense of community and institutional support can each have a direct role in mediating the relationship between concentrated disadvantage and crime, they also have an indirect role by shaping the level of collective efficacy a community possesses. Social networks, however, influence crime solely through the mediating effects of collective efficacy (Morenoff et al., 2001). Collective efficacy translates the opportunities to enact social control into the actual expression of that control. It is the process by which a sense of community, social networks, and institutional resources are mobilized in such a way as to lessen crime.

At some level, the concept of collective efficacy calls to the forefront a key component of early social disorganization theory sometimes lost in the contemporary literature. Beyond economic disadvantage, Shaw and McKay (1942) were concerned with the effects of community heterogeneity. Their hypotheses regarding the effects of immigration on crime, for example, was not due to the assumed criminality of immigrants, but to the difficulty of establishing efficacious social networks (meaning those able to generate collective efficacy) among residents who did not share common cultures, traditions, or even languages.

Areas of Continued Research

Beyond finding support for the broad tenets of social disorganization theory, extant research indicates that rates of crime increase in tandem with many other specific characteristics that create variation among communities. These characteristics represent ongoing areas of continued research on community differences in aggregate crime. Three specific areas of continued research are highlighted here: (1) the role of employment as a stabilizing force in communities, (2) research using a nuanced understanding of the poverty effect, and (3) cross-disciplinary work incorporating crime as a predictor of other aggregate-level differences across communities.

The Role of Work as a Stabilizing Force in Communities

One vein of relatively recent social disorganization research has examined employment as a mechanism of social control. Marginal employment, that which is characterized by low

wages, variable hours, few benefits, limited requisite skills, and constrained mobility, has detrimental effects on both individuals and communities (Crutchfield, 1995). Marginal employment increases criminality by failing to provide disincentives to prevent crime. Individuals with 'good' jobs avoid situations that may jeopardize those jobs, while individuals with 'bad' jobs do not. Communities where large proportions of residents are marginally employed lack the aggregate structure and stake in conformity that communities with higher quality local labor markets provide. Moreover, such communities may promote involvement in a street culture that does not value present or future employment prospects (Jacobs and Wright, 1999).

Poverty and Community Differences in Crime

Poverty has been a central explanatory variable in community crime research since its inception. The conventional ideas then, as now, about the connection between concentrated poverty and crime held that deconcentrating poverty would deconcentrate crime. In more contemporary interpretations, researchers suggest that socioeconomically diverse neighborhoods will generate socioeconomically diverse social networks. These networks will then serve to distribute economic, social, and cultural capital across communities, benefiting those who are poor and those who are not poor alike. The combination of shared resources and efficacious social networks will yield communities with less crime. Recently, however, researchers have begun to study the veracity of these assumptions by examining the formation of social networks within the context of social disorganization theory. Socioeconomically diverse communities are, by very definition, heterogeneous communities. Those living in such communities may experience difficulty establishing efficacious social networks (meaning those able to generate collective efficacy) with others who share their same physical space, but who may not share similar life chances. The question then becomes whether or not heterogeneous social networks can be efficacious networks. Do the protective benefits of decreased, or diluted, disadvantage outweigh the criminogenic risks of heterogeneous social networks?

Crime as an Independent Variable

Finally, having established community context matters, research on neighborhood effects has recently taken a 'process turn' toward explaining *why* communities matter in explaining individual behaviors (Morenoff, 2003: 979). In such research, crime often becomes an independent variable instead of a dependent variable. This perspective has been widely adopted in the public health literature, where scholars suggest that one of the primary ways that aggregate community conditions influence numerous health disparities is by generating stress, citing criminal victimization and the fear of victimization as key stressors. But again, efficacious social networks within communities appear to work to temper the effects of stress (Diez Roux, 2004). While stress-inducing community characteristics, such as crime, can generate negative health outcomes, these effects can be offset by positive social relationships and active civic engagement among residents. This is but one of many examples where the basic precepts of social disorganization theory have been integrated into explanations of outcomes other than aggregate community crime, with criminal victimization and/or fear of criminal victimization operating as predictor variables.

Crime and Different Types of Communities

Just as the scope of the social disorganization theoretical framework has been expanded to include more broadly defined variables, its application has also been expanded to include analyses of specific types of communities. Three examples of research on such specific communities include research on crime in rural communities, public housing communities, and immigrant communities.

Crime in Rural Communities

Much research on communities and crime assumes that since crime is more prevalent in urban communities, the social disorganization framework does not hold for other types of communities, working from the assumption that individuals in urban communities are less likely to maintain social networks, join community organizations, and exert social control over peers. The result is the perspective that urban communities are by definition characterized by a greater degree of social disorganization than rural or suburban communities and hence exhibit greater rates of crime. Despite comparatively sparse research on the role of community correlates in shaping crime in rural communities, there are many reasons to expect some rural communities to mirror socially disorganized urban communities.

Recent demographic changes have created new stressors and strained existing rural resources. While rural areas in many industrialized nations have gained population in recent years, both those areas that experience population growth and those that experience population losses face significant challenges as a result. Areas gaining population have had to deal with an influx of new residents who differ from existing residents across numerous dimensions, not the least of which is ethnicity (Johnson, 2003). In particular, the growth of the minority population has changed the face of rural communities in many countries. Conversely, areas losing population have confronted the problem of maintaining community cohesion as the size of the community has shrunk (Johnson, 2003). Both of these contradictory trends have increased community stressors and strained community resources in the areas they have afflicted.

Economic changes have created even greater challenges for rural communities. Two primary economic changes confronted rural communities during the latter part of the twentieth century. The first was the farm crisis of the 1980s. Continuing the boom–bust cycles that have historically typified rural agriculture, the complex interplay of debt, inflation, and global commodities markets cost many rural families the farm, quite literally (Barnett, 2003). For some rural areas in the United States, however, the losses experienced as the result of the farm crisis were offset by employment gains due to the deindustrialization of urban areas. As manufacturing firms left the United States' industrial rust belt, rural areas, particularly in the south,

enticed firms to relocate with low taxes, inexpensive land, and right-to-work laws only to see these same firms leave the United States altogether in an effort to secure lower labor costs in other parts of the globe.

Both demographic changes and economic changes reshaped rural community institutions, including local governments, families, and religious organizations. The ability of local governments varied across rural areas in their ability to meet demand for services that may have been protective against crime (Duncan, 1999). The capacity of other social institutions to meet this demand also varied. While churches and high levels of religiosity have often been seen as protective factors in rural communities, declines in church attendance led to the decline of the church as a crime-protective institution in rural communities. Finally, the structure of rural families has changed in light of late-twentieth-century demographic and economic shifts. Matching their urban counterparts, rural families face high levels of divorce and single parent households (Lichter et al., 2003), both associated with less supervision of youth and more juvenile delinquency.

Crime in Public Housing Communities

Crime is a serious problem in public housing, with crime rates estimated to be as much as 80% greater in public housing projects than in surrounding neighborhoods (Holzman et al., 2001). Given the violence endemic to some public housing, ameliorating the crime problem in such places has been a central component of policy aimed at eliminating public housing projects or estates in order to break up concentrated pockets of poverty in socially disorganized communities and disrupt cycles of intergenerational poverty. Evidence from three large scale studies in the United States provides mixed support for this policy perspective. These studies are (1) the Gautreaux Assisted Housing Program; (2) the Moving to Opportunity (MTO) for Fair Housing Program; and (3) the Housing Opportunities for People Everywhere (HOPE VI) Program.

The Gautreaux Program moved thousands of project-based public housing residents to suburban and urban nonpoor neighborhoods. In terms of public safety, Gautreaux participants reported less violence and crime, safer streets, and better schools in their new neighborhoods; but residents that moved to the suburbs lost their previous social networks and institutional support systems (Rubinowitz and Rosenbaum, 2000). This became the primary reason for participants to leave the program, choosing to stay close to what and who they knew even if it was a neighborhood with higher crime (Pashup et al., 2005).

The Moving to Opportunity study used an experimental design to examine the causal effects of neighborhood disadvantage on a range of outcomes among public housing residents who relocated voluntarily to other types of communities. Families in a treatment group were given housing subsidy vouchers and required to move into low poverty neighborhoods, those in a second group were given vouchers but no stipulation on where they could move, and those in a control group remained in public housing. MTO findings have been mixed. Treatment group members reported less fear of crime, but no significant improvements for a host of other outcomes, including risk-taking behaviors (Ludwig et al., 2001; Orr et al., 2003).

Finally, the HOPE VI Program sought to reinvent public housing by demolishing large, spatially concentrated developments and replacing them with mixed-income housing, with the objective of deconcentrating poverty (Popkin et al., 2004; Smith, 2002). To assess the impact of this program, researchers tracked a sample of relocated public housing residents from developments that were demolished and rebuilt as mixed-income (Popkin et al., 2004). Like MTO, findings have been mixed, but overall relocation was beneficial for residents, particularly in terms of residing in safer neighborhoods (Popkin et al., 2004). Thus, in sum, research on public housing communities in the United States finds that moving into other types of communities leads to the experience of less criminal victimization and less fear of victimization, but comes at the expense of supportive social networks and engagement in bridging community ties.

Crime in Immigrant Communities

Finally, the origin of community studies of crime developed when the founders of the Chicago School of Sociology observed the social consequences of rapid immigration during the first half of the twentieth century (Park and Burgess, 1924; Shaw and McKay, 1942). Although, even during this period of rapid immigration and pervasive antiimmigrant sentiment, data did not indicate a clearly positive relationship between immigration and crime (Hourwich, 1912), the common assumption was often that immigration leads to more crime across communities.

Contrary to this assumption, contemporary scholarship on crime in immigrant communities repeatedly finds either no relationship or an inverse relationship between levels of immigration and levels of crime. Such relationships are observed in numerous United States cities, including Miami (Nielsen and Martinez, 2009), Chicago (Vélez, 2009), and New York City (Davies and Fagan, 2012). Immigrant settlement in inner-city areas has often occurred in those areas that experienced dramatic population declines and economic disinvestment of the 1970s and 1980s. Consequently, it appears that immigration reduces aggregate levels of crime, in part, by revitalizing urban neighborhoods (Reid et al., 2005).

Summary and Conclusions

Understanding why communities exhibit different levels of crime requires understanding the very fabric of communities. Poor communities are not necessarily violent communities. Nor are immigrant communities, urban communities, or any other broad type of community. To understand variation in crime rates across communities, one has to examine how the combined influence or social networks, institutional support mechanisms, sense of community, and collective efficacy operate within a community to create social environments that are either conducive to or protective against crime.

Communities of Practice

This article is a revision of the previous edition article by E. Wenger, volume 4, pp. 2339–2342, © 2001, Elsevier Ltd.

Abstract

Communities of practice (CoPs) have emerged as an influential concept to foster both individual and group knowledge within a social learning system. They have three fundamental elements: a 'domain' of activity or knowledge that creates a sense of common identity, the 'community' who are the members who care about that domain, and the shared 'practice' developed by community member. CoPs are established or emerging in many educational, government, and industry contexts. Leadership has been identified as an important success factor, and social media and mobile devices now are generating a range of opportunities for members to engage in their CoPs.

What Are Communities of Practice?

As social beings we are involved in many communities, such as professional associations, community or neighborhood watch, religious groups, or hobbies, such as a garden club. However, not all such communities are communities of practice (CoPs). A community of practice (CoP) is a unique combination of three fundamental elements: a 'domain' of activity or knowledge that creates a sense of common identity, the 'community' who are the members who care about the domain, and the shared 'practice' the community members develop to be effective in the domain (Wenger, 1998). The term 'communities of practice' emerged from Lave and Wenger's (1991) study that investigated the apprenticeship model learning, which showed that, rather than the one-on-one master/apprentice model, it was a complex set of social relationships within the whole practicing community that supported learning and membership of the knowledge domain and practice field. The identification of CoPs as a concept and social system (Wenger, 2010) that can be identified and cultivated has created a mechanism to study both individual and social learning behaviors across a range of contexts. The CoP concept is based on the study of the social nature of human learning inspired by anthropology and social theory (Lave and Wenger, 1991; Vygotsky, 1978; Wenger, 2010). Since 1991 Etienne Wenger's ongoing practice, research, and publications have provided the foundation for much of the growing investigation and implementation of CoPs in many contexts, including health care, education, local, national, and international government and business.

CoPs and Social Learning Systems

Thinking about CoPs as social learning systems enables us to reflect on both individual and group learning, and the relationships, interactions, and learnings that we forge or experience within these social systems. Wenger (2010: p. 179) suggests CoPs "exhibit many characteristics of systems more generally: emergent structure, complex relationships, self-organization, dynamic boundaries, ongoing negotiation of identity and cultural meaning, to mention a few." As CoP members explore and grow their domain knowledge over a sustained period of interaction, they develop trust, a sense of identity, community, and also resources that document a shared history of learning, thus creating a dynamic social structure that is a CoP. Individuals bring their knowledge, experience, and perspectives and negotiate the meaning of domain knowledge and practice with members, thereby building both their identity within the CoP and jointly creating a unique identity for the CoP. Wenger (2010: p. 182) notes that "learning is a social becoming."This individual and group identity reflects the complex relationship between the social and the personal and locates CoPs firmly in the social and behavioral sciences.

Stages of CoP Development and the Three Elements as an Organizing Structure

A CoP may emerge from a particular idea or issue, or be triggered by interactions among colleagues working together to explore an opportunity or solve a problem. This provides the impetus to start the CoP and often one or two enthusiasts emerge as CoP leaders, facilitators, or convenors. From start-up, the CoP usually moves through a number of stages or phases. Snyder and Briggs (2003) suggest that CoPs, like all living things, grow through distinct phases of development (discovery, coalescing, maturing, stewarding, and legacy), so each phase needs to be understood to address the issues and opportunities at each phase. Wenger et al.'s (2011) CoP phases of development include establishing the potential, coalescing, active, dispersed, and memorable, and these stages have been adapted and restructured to suit the context or social system of specific CoPs. McDonald (2012) used the CoP stages – initiation, creation, infancy, maturity/sustaining, and recreating – as an organizing structure to develop leadership resources, available at (http://www.usq.edu.au/cops/resources/altcfellowship). Choosing the most appropriate approach may be challenging as resources range from discussions of the theoretical foundations to practical guidelines and templates for starting a CoP. Identifying the type of CoP to be established is the first step and scoping the specific context and support available are important considerations for CoP leaders.

One approach that has proven effective in the author's experience is the adaption of the three elements of CoPs as the organizing structure for colocated CoP meetings (McDonald and Star, 2008). It is worth noting that these meetings or gatherings are quite different from the standard business format. In a CoP priority topics and agendas are established by members and time is allocated for each of the three CoP elements – knowledge domain, practice, and community building. At the initial meeting members identify and negotiate the domain-focused topics to be addressed by the CoP, location and times to meet, potential members and stakeholders, communication processes and alignment (or not) with institutional goals and mission. The elements of *domain* of knowledge, such as first year students, mobile learning or research supervision, establish the common focus and sense of common identity, the *community* consists of members involved in that domain and who meet over time and a sense of community, and the shared *practice* is what members bring to, and develop together, to be effective in the domain.

A common time allocation for physical CoP meetings is either 1.5 or 2 h, with approximately 30 min allocated for each element. The allocation of additional time to share emerging issues, such as a round of 2 min at the start for each member to share 'what's on top,' the current priority in their practice, allows time for items not set as a priority at CoP start-up. The unstructured community time, with quality refreshments, provides a time for informal networking and knowledge exchange. This is a commitment to build social learning and community bonding which is never usually factored into traditional meeting agendas. Community time provides the foundation for building the social learning system. Items for the domain and practice elements are usually identified by members at start-up, and may involve invited domain speakers or members presenting in their area of expertise, then the members share how they implement activities in their practice. For example, the meeting focus may be on implementing a student group learning process, so someone with a proven track record is invited to build the domain knowledge of members, and in the sharing practice time members share their experiences and plan applications of the new knowledge. This knowledge is captured and made available as a permanent record of CoP activity and as a resource for members. This approach has proven to be a powerful and sustainable application of CoP theory to higher education practice, and was noted as a 'unique approach' by Etiienne Wenger (2008), and is also being applied in digital communities (Reushle, 2011).

CoPs Established and Emerging in Many Contexts

CoPs are well established in business, government, healthcare, and international and national projects such as World Bank and World Health, with much of the early CoP literature (Wenger, 1998; Wenger et al., 2002, 2009) relating to CoPs in these contexts. Each context will influence the structure, operation, and impact of the CoP, depending on the specific cultural, political, and institutional environment. More recently, CoPs have emerged as an approach to foster learning communities in education, providing some dilemmas as CoPs, with their more informal, member-driven, social learning system, cut across established, hierarchal, and institutionalized educational systems. Issues of power, competency, and legitimacy can cause tension between the CoP and traditional, institutional structures, as knowledge emerging from the 'coal-face' practice of members challenges the top-down, institutionalized knowledge and systems.

In Australia higher education CoPs are gaining momentum as a way of creating social learning communities to support educators working to improve learning and teaching in, including a number of projects sponsored by the Australian Government Office of Learning and Teaching (OLT). An example is the OLT funded project that focused on clarifying and building the leadership capacity of facilitators of learning and teaching CoPs (McDonald et al., 2012).

Current Discourse around CoPs

The current interest in CoPs, and their implementation in various contexts, has generated debate about what does and does not constitute a CoP. The initial concept identified by Lave and Wenger (1991) described CoPs as spontaneous or organic, emerging from shared interest, practice, and ongoing interaction, and an organic CoP is held up by some (Stamps, 2000; Roberts, 2006) as the only 'true' CoP. However, CoPs as a simple social system are found in all contexts, and as their value in building individual and institutional knowledge becomes more widely recognized (Cox, 2006; Iaquinto et al., 2011; McDonald et al., 2012; Wenger et al., 2002; Wenger, 2010), there is increasing interest in supporting emerging or existing CoPs, and also cultivating 'intentional' CoPs. McDonald et al. (2012: p. 22) found that there are three types of higher education CoPs, as noted in **Table 1**.

The debate about what constitutes a 'real' CoP is a result of the shift from an analytical title used to define CoPs as a concept, to a more practical, or instrumental, application of

Table 1 Types of community of practice (CoP) and contextual issues

Type of CoP	*Organic*	*Nurtured/supported*	*Created/intentional*
Structure	Bottom-up	Modified bottom-up	Top-down
Support level	Minimal	Subsidized	Provided
Membership	Voluntary	Voluntary/suggested	Encouraged
Themes	Discipline-related	Discipline or issue related	Guided issues and cross discipline
Agenda	Self-determined	Self-determined/steered	Guided theme
Timing for outcomes	Self-determined	Self-determined and funding related	Short-term rather than long-term

the concept. Wenger (2010: p. 192) says "the concept of community of practice started out as an analytical concept, giving a name to a phenomenon that already existed. Now it is often used with an intention to create, cultivate, or capitalize on the process – almost as a technique." There is a danger that the uninformed, instrumental application of the concept may lead to a dilution of the concept (Hughes, 2007) where it is used to serve top-down corporate needs, rather than to create a social learning system. However, much of the debate seems to be about the different types of CoPs (Burch et al., 2012), reflecting the tension between CoP theory and how it has evolved in practice, rather than what actually constitutes a CoP. While there has been obvious advantages to cultivating CoPs to grow and support individual and institutional learning systems (McDonald and Star, 2008), in the instrumental application of the concept, there may also be a mismatch between the informal, peer-to-peer (horizontal) structure, with a member-initiated agenda and focus, and the top-down, hierarchical (vertical) and instrumental imperatives. Langelier (2005: pp. 16–17) discusses the subtle distinction between integration and institutionalization of CoPs, suggesting that a distinction needs to be made between the institutionalization of CoPs themselves, and the institutionalization of their existence in the institution. If alert to this dilemma, CoP members can ensure the integrity of the CoP by communicating the individual and institutional benefit of the CoP, and by educating management about the unique operation and value of CoPs. On a more positive note, even the instrumental introduction of CoPs will create dialogue around the way both individuals and the institutional managers view and foster learning, opening the door for the integration of horizontal (CoP) and vertical (institutional) social learning systems.

Role of Leadership of CoPs

Effective leadership of CoPs has been identified as an important contributor to the success and sustainability of higher education CoPs (Cox, 2006; McDonald and Star, 2008; McDonald and Palani, 2011; McDonald et al., 2012; Ortquist-Ahrens and Torosyan, 2008; Wenger, 1998). Wenger et al. (2009: p. 10) note that "leadership is an essential ingredient in a community of practice, whether formal or informal, concentrated in a few people or broadly distributed." Leadership of CoPs requires a combination of leadership attributes and skills, including the ability to support member goal and activities to build an effective social learning system, as well as positioning the CoP to succeed within the broad institution context. It will also require knowledge of the theory of CoPs so the leader can identify the type of CoP and particular skills and leadership attributes required for different stages as the community evolves within its broad context.

Where Are CoPs Heading in Our Digitally Connected World?

Social media and new mobile technologies provide opportunities to engage in national and international CoPs, any time and any place. This creates opportunities and challenges around the viability of learning communities. Also, there is an increasing interest in individual or personal learning journeys, supported by accesses to mega amounts of information and casual interactions with others via global networks. For example the increasing availability of Massive, Online, Open Courses (MOOCs), where community building and group activities are rarely components of the learning experience. On one hand, social media can support both group and one-to-one learning typical of CoP activities, as well as provide a rich range of media and opportunities to share and communicate the learning generated with both digital and colocated CoPs. On the other hand, access to such a vast range of knowledge and networks can be daunting and draining, with learning opportunities swamped by time consuming internet surfing and sense of aloneness in digital world. As individuals we decide how we will focus our participation in social learning systems; it may be by a leadership role, contributing as full or casual members or surfing through learning environment, picking up or sharing ideas as we travel our learning journey. Wenger (2010: p. 196) puts forward the idea of 'learning citizenship' and suggests that to contribute to the learning capability of social learning systems is 'a personal responsibility that comes with social participation,' which will have a positive impact on the learning capability of both personal and social systems.

Community and Media

Gustavo S Mesch, University of Haifa, Haifa, Israel

Abstract

This article examines the role of media on the local community from three perspectives. One approach examines how different media outlets affect the identification and participation of residents in the local community. The second examines the characteristics of online communities and its main features. The third approach looks at the emerging role of online geographically based communities on the social integration of residents in the local community. Directions for future research are provided.

Concern about the role of the media in the formation and maintenance of the local community has been a central topic of interest in the social sciences since the early years of the twentieth century. Scholars associated with the Chicago School of Sociology were pioneers in the field. Generally speaking, the study of the association between the use of media and social integration in the community has focused on three different areas. One line of research has followed the tradition of urban studies, focusing on the role of the press and social media in the involvement in and attachment to the local community. A second line of study began in the early days of Internet adoption and transitioned to the study of online groups and virtual communities that exist regardless of physical propinquity. Finally, a more recent development has been the understanding of the role of locally based online communities for the process of social integration in the local community.

This article will provide a concise review of some of the theoretical frameworks and research findings based on these three distinct but complementary traditions.

The Media and the Local Community

In the early years of the twentieth century, studies in sociology and geography were interested in the characteristics of media audiences and the effects of media consumption on the local community. Robert Park (1922), studying the US as an immigrant society, investigated the role of the community press in identity formation among immigrant groups. He observed that newspaper reading was more characteristic of residents of urban areas than rural areas and that urban residents were interested in news from outside the area. Later, Robert Merton (1957) distinguished between localites and cosmopolitans. Localites were more oriented toward the local community, engaged in more locally based social activities and they saw the local newspaper as the source of local news. In contrast, cosmopolites were concerned with social activities on a broader scale and were more likely to consume media outside their local area. Janowitz (1952) then made an important contribution to the study of the role of media and community structure by investigating the association among media, a community's social organization and attachment to place. The systemic model of community attachment ascribes a central role to the process of socialization in the local community, participation in locally organized activities and involvement in local social networks. The model conceptualizes community as resulting from residents working together on collective problems. Participation and involvement in local issues vary depending on the stakes in local issues and involvement in local social ties. In this model, newspapers and the local media play a central role in integrating individuals into the community and contribute to the development of a shared belief system of values and norms supporting the process of socialization and social control in the local community. Janowitz found that community integration and involvement in local issues are associated with greater attention to the local press.

A serious problem in identifying the role of the press and media in a community's social organization is determining the direction of the effects. In other words, does local media consumption lead to social integration, or are the more active and involved residents also more likely to consume local media? More recent attempts have tried to clarify this issue. Stamm et al. (1997) developed a model that attempted to understand (1) the role of the media in social integration into the community and (2) the role of social integration into the community on media consumption. These relationships have become complex because of the effects of globalization, geographical mobility, suburbanization, and the increasing scale of human activities on local affairs. In their view, there are four mechanisms that link the media to the local community (Stamm et al., 1997). First, the power of local media lies in its ability to identify problems that need community attention and bring them to the attention of the public. Identifying local problems and expanding awareness helps community members become part of the instrumental solution to these problems. Second, the local media help identify local groups and those with influence, and bring them together. By identifying the key actors and issues, media stories support the efforts to mobilize local residents for action. Third, the local media can identify individuals with specific skills and specialties. Finally, by reading the local newspapers, residents have time to think about local problems. In his study, Stamm (1985) found that local media consumption was associated with community integration, but this correlation was modest. Furthermore, there was an association between interpersonal communication, community integration, and collective action. Local media consumption was associated with community

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95074-8

integration through an increase in locally based interpersonal communication, a central feature of neighboring.

Regarding the fundamental issue of whether communities are a result of newspaper readership, or newspaper readership is a determinant of community ties, Stamm et al. (1997) concluded that most likely, the relationship is cyclical and works both ways. Those who read newspapers tend to be more connected to the local community, and those connected to the local community are likely to read their local newspapers.

A common assumption in the literature is that people are linked to their community through the local media that inform them about their environment and interpersonal networks that link them to neighbors, offering them the opportunity to share their political beliefs, and exposing them to the beliefs of others. Nevertheless, in the wake of the major changes that have occurred including media convergence and globalization, the local media has changed as well. In many cities in Western countries, the local press has retained a print edition and added an online edition. Despite the large-scale changes, these media are important communication channels for locals as well as national political actors. In their study, Skogerbø and Winsvold (2011) focused on the role of newspapers as they move to online platforms. Their findings show that print editions are still read more than online newspapers, confirming the continuing dominance of the print versions. Fewer people use the online newspapers as their primary source of information. However, both the general and elite audiences stated that online newspapers were a valuable addition for rapid updating and searching for news and historical information. Skogerbø and Winsvold also found socioeconomic differences between readers of the online and print editions. Print and online audiences read different types of content according to their age, social background, gender, and political activity. Regional and local newspapers were still viewed as mediators of identity and belongingness to the place, but there were differences between online and print audiences. Community attachment and reading the local newspaper correlate with one another. Thus, the local online audiences are different from the print audiences in many other respects too. The two platforms seem to evoke different uses and preferences among audiences, suggesting that people regard online and printed newspapers as different media.

Another major conceptual approach to the link between the media and the local community is the communication infrastructure theory (Ball-Rokeach et al., 2001). According to this approach, a 'media system' is an information system that individuals access in order to obtain the information that is necessary for achieving their goals. Communication infrastructure theory defines the media as including macro- and mesolevels. The macrolevel includes mainstream television and newspapers. The meso level includes local or ethnic media, including new communication technologies. The communication infrastructure is defined as a storytelling system set in a communication action context (Ball-Rokeach et al., 2001).

The storytelling system covers multiple levels, and each level is defined by the stories that are told by each actor. If a television station broadcasts stories that cover a nation, it is considered macrolevel media. On the other hand, if another television station focuses on stories about a local area, it is considered mesolevel media. Furthermore, this perspective includes not only macrofactors, but also local conditions such as the existence of public facilities, schools, and technological infrastructures that influence individuals and communications. The community infrastructure approach examines the communication infrastructure with an eye to two central factors. The first is the neighborhood storytelling network, which consists of three key storytellers: (1) the residents and their network of family, friends, and neighbors; (2) the community and nonprofit organizations that are located in the neighborhood and serve its residents; and (3) the media that target a particular geographic area. When these storytellers create a conversation about the neighborhood – its problems, opportunities, and events – people have a sense of belonging to a community. According to this view, storytelling is the basic way that communities are created.

The second component of the communication infrastructure is the communication action context, or the communication environment in which storytelling occurs. This environment may either constrain or facilitate the storytelling network. It consists of many elements, including the cultural diversity of the community, work conditions, the schools, libraries, parks, and other public spaces, the services available in a community such as health care services, retail stores and recreational facilities, the transportation system, and technological resources, such as Internet access. This last element is a key factor in this theoretical framework. Researchers have explored the nature of individuals' connections to Information communication and technology (ICT) and how those connections are embedded in and affected by the complex and multilevel communication infrastructure in which we live (Ball-Rokeach et al., 2001; Jung et al., 2001). According to the communication infrastructure theory, local communities differ in their communication opportunity structures. Some environments provide easy connections to necessary and useful communication channels, but others make it difficult to access such channels. Differences in communication opportunity structures are associated with differential access to social, political, cultural, and social capital resources (Kim et al., 2006). For example, Kim et al. (2006) found that the Internet was more integrated into the communication infrastructure of white neighborhoods than immigrant neighborhoods. Their study suggests the possibility that in ethnic neighborhoods, ICT creates a 'magnifying glass effect.' While it does not deter people from civic participation, ICT have a positive additive effect only on those people who already have connections to communication resources.

Virtual Communities

During the rapid expansion of access to and use of information and communication technologies, academic attention and interest has also focused on social groups that are not bounded by a specific geographic place. Members of such groups participate in computer-based social interactions with people they have often never met face-to-face. The participation of individuals in geographically dispersed groups through a mediated form of communication is not new. For example, at the beginning of the twentieth century, wireless radio was used to transmit long distance communications, and amateur radio

operators worldwide used this technology to chat and exchange information (Stephens, 1995). Nevertheless, the development of the Internet and World Wide Web is important because it allows reliable access across any distance in real time. A virtual community is a voluntary group of individuals with shared interests who interact with one another through computer-supported networks for a relative long period of time, exchanging sociability, social support, and resources. Through this social interaction, common ties and some social organizations develop (Driskell and Lyon, 2002).

The use of the term 'virtual community' created a controversy about whether online groups are communities and the degree to which a community can exist without a shared physical locality. In fact, conceptual models in the field of community studies emphasize shared needs and concerns over propinquity as the basis for a community. The idea of a "community without propinquity" developed by Melvin Webber (1964) maintains that individuals are members of an overlapping range of groups and create social networks that are not limited to physical location. According to this idea, a community should be one oriented toward social process, social interaction, and social networks. Rather than propinquity, the emphasis is on the access to social interactions and resources as the necessary condition for the formation of a community (Wellman and Whortley, 1990). Virtual communities have enjoyed a substantial amount of public and academic interest. Despite the nature of the communication, members of virtual communities seem able to develop intimate and personal relationships on the basis of common interests, not geographical location. Thus, an electronic space can be regarded as a shared space to which motivated actors are drawn in search of specific formal activities, such as the search for information, or informal activities such as social support and entertainment according to their particular interests.

An innovative aspect of the Internet is the proliferation of special interest groups devoted to almost any imaginable topic: music genres, sports and gardening, dating, parenting and pregnancy, chronic and life-threatening diseases, and professional interests. Online communities have become spaces for social interactions in which friendships and even close relationships are created and maintained (Mesch, 2007). Perceptions of shared interests and concerns are probably the most robust variables that the sociological literature has identified as conducive to the formation, development, and stability of interpersonal relationships. In fact, the chance of finding people in one's local community who share one's needs or interests may at times be slim. On the World Wide Web, the chances of forming a community of like-minded people are much better.

Although technology now allows interactions through audio (Internet phones) and video (Webcams), most communities rely on textual communication complemented by the use of pictures and movies. Such communication often consists of messages posted and stored on a server. Members can choose to receive the postings directly and read them at their convenience.

Virtual communities function as social spaces, providing two different broad types of resources: socioemotional support and the exchange of information and resources. These functions are not mutually exclusive, and in many communities both are performed. Participation in online communities can be extensive, and participants spend varying amounts of their daily lives involved in such activities.

Certain features of the new electronic communication have made participation in online communities attractive. The Internet can support various forms of communication including real time as well as delayed communication, person-to-person, person-to-people, and people-to-people communication. Thus, the access to information, entertainment, and social support is personalized, and provided round the clock whenever the individual needs it or seeks it. Furthermore, the communication of many with many in real time supports the kind of interaction required for the formation of a repetitive pattern of social interaction. It promotes the development of a common identity based on a shared interest, norms of behavior, and a social structure characteristic of the concept of community.

At the same time, it is important to acknowledge that community formation online does pose some problems, as we will see in the next section. First, face-to-face communication is a rich communication channel because it uses both verbal and nonverbal cues such as voice inflection, body gestures, nonverbal messages, immediate feedback, and bidirectional communication. In contrast, computer-mediated communication is devoid of personalization, making it difficult to convey personal feelings and emotions or to tailor messages to the needs of the receiver's current situation. The lack of cues can lead to misunderstandings. In order to overcome this problem, users must learn how to communicate using a shared system of symbols.

Another barrier to the formation and maintenance of virtual communities is the 'lurker' problem. While most activities in the community involve at least reading the participants' posts, not all participants contribute equally. Some lurk in the background, limiting their participation to the passive role of reading other messages but never posting their comments or original ideas. Nonactive participants in online communities become almost invisible to the other members because they leave no trace of their presence. While passive participants are part of the community in that they are often looking for information, when they constitute the overwhelming majority of the group, they endanger the group's existence. They leave the setting of the group's agenda to a few vocal people. In addition, passive participation maybe contagious, discouraging the participation of others. Some communities address this problem by restricting participation to only known and trusted individuals or creating a tiered system in which access to general postings is free to all, but more personal and sensitive material is by membership or invitation only.

In the past, another threat to virtual communities was identity deception. In any group, the purpose of the online conversation is the creation of a unique social system founded on a shared identity and norms of behavior. These features are problematic in online communities in which there are no clues about the participants' social status. Knowing the identity of others with whom one communicates is essential for understanding and evaluating the interactions. However, in the nongeographic world of virtual communities, identity is also ambiguous. Many of the basic clues about personality and social roles that we are accustomed to in the physical world are absent.

Finally, the extent to which norms are created in online communities is important both theoretically and practically. Early conceptualizations of computer-mediated communication argued that the absence of social and contextual cues about the communicators creates a serious problem when it comes to the formation of norms and even adherence to normative behavior. When indicators of social status and hierarchy are lacking, nonnormative and even flaming behavior is likely to occur. Nonnormative behavior, norm violation, and flaming are examples of negative interactions that undermine the sense of belonging to an online community. A viable community requires the formation of shared bonds that depend on messages sent to everyone simultaneously. Established norms that regulate the posting of messages, an accepted language of interaction, and even problem-solving techniques are needed. The sustainability of an online community requires sustained social interactions and the formation of shared collective norms and identity. For this reason, only a small number of online groups ultimately develop into online communities.

Thus, we need longitudinal studies about the creation, development, and decline of online communities in order to improve our understanding about the development of norms and collective identity. Longitudinal studies will provide important insights into the factors that explain why some communities survive over time while others do not. At the same time, we must acknowledge that the boundaries between online and off-line relationships are becoming blurred. As residential mobility increases, online communication helps us keep in touch with people we actually know. In the same vein, geographic communities tend to create shared electronic spaces in which to interact.

Geographically Based Online Communities

A third line of research has investigated how the use of new information and communication technologies by community members affects the local community. The use of ICT to support the local community is usually referred as community networks. A key distinction between online communities and community networks is that the former are based entirely on computer-mediated communication, while in the latter, the online communities are rooted in proximate geographic relations. In community networks, people are already part of one another's social networks and also have face-to-face interactions (Kavanaugh et al., 2005b).

Two of the major potential benefits of community networks for proximate communities are (1) increasing and promoting civic engagement and interactions among citizens; and (2) enhancing citizens' participation in community associations, political initiatives, and similar community activities (Putnam, 2000). Comparing the characteristics of online groups and community networks, Etzioni and Etzioni (1999) argued that the proper combination of both face-to-face communication and computer-mediated communication is more promising for creating a community than either of them separately. Indeed, according to communitarians, online and mobile communication may be a key element in revitalizing local communities and promoting democracy.

Unlike claims previously raised that the Internet has a negative effect on the quality of life in general, and on the social relations aspects of politics in particular, empirical evidence consistently indicates that community networks promote civic engagement and social interaction through residents' participation in community activism (Kavanaugh et al., 2005a). Nevertheless, scholars have yet to document the exact nature of the association between Internet use, social capital, and civic engagement systematically. It appears that Internet use is associated with 'participatory social capital.' Furthermore, there is a positive association between online and off-line voluntary participation in organizations. In a compelling study using cross-sectional and panel designs, Shah et al. (2005) demonstrate that online media complement traditional media in fostering political discussion and civic messaging. These two forms of political expression, in turn, promote civic participation. Similarly, in their Blacksburg Electronic Village study, Kavanaugh et al. (2005b) found a significant association between residents' community involvement and civic engagement, and the residents' effort to stay informed about community events and activities; membership in voluntary associations; level of personal activism in the community; collective efficacy in the community's ability to manage itself; and the use of the Internet for political and civic purposes.

From these studies, we learn that participation in local activities is not technologically determined. It is not Internet use in and of itself that increases participation in the local community. However, civic participation and involvement in local activities is more likely when Internet use is embedded in social relations and expectations. Individuals who are already active in the local community and interested in community life also tend to be members of and hold positions in community associations. Certainly, informed activists with memberships in multiple groups become more involved in local issues once going online, whereas nonactivists become less involved once online (Kavanaugh et al., 2005a). In other words, according to these studies, online communication is a facilitator, but not a necessary condition of civic involvement. Belonging to multiple groups or organizations facilitates the flow of information across a community and strengthens the sense of commitment to the local community. As a result, members of multiple organizations are more likely to use the Internet for local communication and to be active and involved in the community (Kavanaugh et al., 2005a).

Do community networks improve the quality of neighborhoods? The Netville study was one of the first studies to test the impact of new information and communication technologies on social relationships at the neighborhood level (Hampton, 2007). It was a natural experiment in which residents who moved to a suburban community in Canada were promised free broadband access and online services. The control group consisted of those who did not have an Internet connection. The results of the Netville study suggest that the Internet facilitates local community connections, not just long distance ones as was originally assumed. When wired residents were compared to nonwired neighbors, those with access to the Internet were more involved with their community. They recognized three times as many neighbors, talked to them more times, visited more in person, and called them on the telephone more often than those who were not connected to the Internet (Hampton and Wellman, 2003).

Another study, the e-neighbors study, investigated four neighborhoods in the Boston area. This was a longitudinal study designed to understand the extent to which the Internet facilitates interaction at the neighborhood level. The neighborhoods were similar in terms of socioeconomic status, but differed in their location and type of housing. Two were inner city neighborhoods and two were suburban, including one apartment building and one gated community. Three of the neighborhoods were given access to a neighborhood e-mail discussion list and a neighborhood Web site. The e-neighbors study found that Internet use became increasingly embedded in the neighbor networks. Furthermore, over time, those who were early adopters of the technology were more likely to know more of their neighbors. The study concluded that Internet use encourages the formation of local networks as well as participation in political discussions and engagement in political action. The study's main conclusion was that online activity increased local awareness and the rate of social interaction among neighbors (Hampton, 2007).

From these two studies, we can see that the use of media in the local community is associated with the formation of a sense of community, a positive emotional bond that develops between individuals and groups and their environment, and reflects identification with place. One very important question is what is the role of community networking in the formation and support of this sense of community? The Netville study (Hampton, 2007) shows that Internet connectivity supports a variety of social ties, both strong and weak, which can be instrumental, emotional, or social. Locally based ties are maintained via a combination of online and off-line interactions. The findings show that in addition to the ability of the Internet to serve as a global communication technology, a great deal of online activity takes place between people who live (or work) near one another (Hampton and Wellman, 1999). Wired residents are more likely than nonwired ones to know more neighbors and socialize with them more often (Hampton and Wellman, 1999, 2001). Other studies provide empirical evidence demonstrating that the use of e-mail lists can facilitate the formation of citizen associations at the local level and support their activities. Citizen associations use the Internet to locate and attract individuals and groups, provide a forum for the open discussion of plans of action, disseminate information about the events and activities of the group, and provide an opportunity for community participation and the expression of a wide range of ideas.

In sum, there is a long tradition of theoretical frameworks about the effect of media on community life. Local media promote the formation of local communities and communities without propinquity. For locally based communities, the media is an agent of socialization, promoting the identification of local problems, and providing an infrastructure for the formation and maintenance of a network of social ties that promote attachment to the community. Studies have demonstrated that the Internet is a technological infrastructure that promotes the formation of communities without propinquity, fosters the exchange of information, and provides resources for social support. It is often assumed that Internet use in and of itself increases communication among neighbors and participation in the local community. However, according to the participation hypothesis, Internet connectivity provides only the access to the opportunity for participation. Access to the Internet allows people to participate in locally based e-mail lists or forums that provide local information and that link residents to their neighbors. Thus, on a local level, the Internet serves as an intervening mechanism, adding to and amplifying participation and involvement in the local community. In addition, the findings consistently indicate that once residents participate in a geographically based online community, the likelihood of membership in locally based organizations increases and is followed by community attachment.

Community and Society: History of the Concepts

Bo Stråth, University of Helsinki, Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Community and society are key concepts in sociology, political theory, and philosophy of history. In ancient Greece, community and society were kept together in one concept. Translated into the political organization of the Roman Republic and Empire, the two concepts began to take on various meanings although without clear distinctions. During the nineteenth century community and society split up and had become counterconcepts expressing social and institutional alternatives. The roots of this separation were developed already in the eighteenth century. Together with another, closely connected, couple of counterconcepts, state and society, they played a crucial role in the reflection and the theory building in social sciences with clear ideological and political implications. This article discusses the contradictory and supplementary views on the two concepts expressed by philosophers like Hobbes, Spinoza, Locke, Kant, Smith, Hume, Ferguson, Fichte, Herder, Hegel, Durkheim, Marx, Engels, Tönnies, Weber, Simmel, Parsons, and König, and ends with a connection to the debate between the communitarians and the libertarians during the last decades of the twentieth century.

Community and society are key concepts in sociology, political theory, and philosophy of history. In antique Greece, community and society were kept together in one concept. Translated into the political organization of the Roman Republic and Empire, the two concepts began to take on various meanings although without clear distinctions. The synonymity – and the ambiguity – continued with the scholastic philosophy. In the eighteenth century the complexity of the conceptual field around the equivalent terms of community and society had increased and included communion, participation, joining, taking part, sharing, liaison, union, corporation, cooperative, friendship, brotherhood, fellowship, etc. Rooting in the eighteenth century but explicitly only during the nineteenth century community and society split up and had become 'counterconcepts' expressing social and institutional alternatives. Together with another, closely connected, couple of counterconcepts, state and society, they played a crucial role in the reflection and the theory-building in social sciences with clear ideological and political implications. This article discusses the contradictory and supplementary views on the two concepts expressed by philosophers like Hobbes, Spinoza, Locke, Kant, Smith, Hume, Ferguson, Fichte, Herder, Hegel, Durkheim, Marx, Engels, Tönnies, Weber, Simmel, Parsons, and König, and ends with a connection to the debate between the communitarians and the libertarians during the last decades of the twentieth century.

Community and society are key concepts in sociology and political and historical philosophy. In antique Greece, community and society were kept together in one concept: *χοινωνι΄α* (Choinōnia). The antique Greek political philosophy did not distinguish between the institutions of community and society. *χοινωνι΄α* was translated into Latin as sometimes *societas*, sometimes *communitas* without clear distinction. With Thomas Hobbes (1588–1679) and Baruch Spinoza (1632–77) in the seventeenth century nature and natural rights disappear as explanation of human collectivity. With the exception of the family all forms of socialization and communalization (collegium, corporation, craft, parish, municipality, partnership, trading company, etc.) were secondary formations within a state federation (*civitas*, *res publica*) constituted through a social convention. Hobbes talked about 'systems of people, numbers of men joined in one interest, one business.' Instead of the concept of society understood as synonymous with community a new concept of society emerged based on a conventional meaning identical to that of the state in the modern sense of the word.

From the middle of the eighteenth century and increasingly from the 1850s society and the social were seen as taking shape between individuals or households and the political order. Almost all social thought during this period was preoccupied with conceptualizing the collective entities that emerged within the 'social' in order to describe and analyze their nature, stability, and ties of cohesion. Besides community and society, concepts like nation, class, and culture were suggested. Societies were seen as organized by division of labor and social interests, by class struggle, or by cultural–linguistic identity. This was the more general framework of the debate on community and society.

John Locke (1632–1704) emphasized the transformation from the traditional view on social relationships, based on natural right, to the modern thought based on rationalism and positive law, and replacing Aristotle's teleological view with the functional idea of collective security. The emphasis on collective security should be seen in the context of the growing role of private property. This development, wherein political philosophy society had become the preferred concept, did not mean that community disappeared. With the exception for political economy, where 'community' was narrowed down to trade company, the definition of society as community remained in everyday language until the end of the eighteenth century. Immanuel Kant (1724–1804) viewed society, in its context of being based on reason and conventions among individuals, as a dynamic totality, the elements of which acted with and against one another. The construction of community for social exclusion and protection meant both inclusion and exclusion, the identification of both 'with whom' and 'against whom.' The 'unsocial sociability' (*ungesellige Geselligkeit*) of humans drove them to form societies. However, this drive toward convention-based collectivity provoked resistance, and the threat of the dissolution of the society was permanent. Kant's view was in this respect close to the school of English-Scottish moral philosophers (Adam Smith (1723–90), David Hume (1711–76), and Adam Ferguson (1723–1816)).

Kant's question about a perfect society based on the free interaction among individuals was taken up by Johann Gottlieb Fichte (1762–1814) at the beginning of the nineteenth century and put into a historical and linguistic-critical context. Although Fichte often used society and community as synonymous terms, he exposed the two concepts, and that of state, to linguistical–critical scrutiny observing the prevailing conceptual confusion.

As far as the German-speaking area is concerned, around 1800 Johann Gottfried Herder (1744–1803) suggested a distinction between community and society. His point of departure was the state–society connection, where 'state' emphasized the unity and closure of the collectivity, while 'society' had a focus on the multiple and open forms of collectivity including those based on the individual rights. In order to describe the relationship between state and church, Herder used society, based on Enlightenment reflection on the contextuality and historicity of religious forms. In order to emancipate the spirit and the mind, the *Geist*, from its entanglement with the state, and to rediscover the suprahistorical core of Christianity, Herder required the separation of society and community, *Gesellschaft* and *Gemeinschaft*, where the latter term was used to describe the community of spirits independent of the state. Herder's distinction, which again took up the old Greek and Biblical-Christian *χοινωνι΄α* concept and infused it with new meaning, failed however to go beyond a specific religious vocabulary.

Kant's moral philosophy provoked criticism from G.W.F. Hegel (1770–1831), who rejected the idea of the autonomous individual. In Hegel's view the individual is certainly rational, although rationality is historical and *transindividual*. The normative and legal order of a society could not have its point of departure in the idea of its individuals as a priori free, equal, and rational. Humans are free only within a morally strong community. Society is not based on convention but on morality. Such is Hegel's view. The human effort, to be recognized at individual levels, results in the emergence of various communities, which are kept together by morally strong virtues, *Sittlichkeit*. The social community was linked to an ethical dimension, which, according to Hegel, appeared in various shapes through history, which was nothing but the development toward higher forms of ethical realization. The highest stage in this historical development was the state, which gave all its citizens true freedom through the confirmation and recognition of them in a meaningful totality. The individual is emancipated through subordination in the collective realization of *Sittlichkeit*.

From this condensed rational–romantic version of community, inspiration could be picked up a century later in Germany for extreme versions of the concept, where it was linked to the *Volk* ('people') concept and political action orientation. The difference between the individualistically oriented Kant and the collectivistic view of Hegel is not restricted to German history but is however more general and has been discernible in two alternative world views on community and society ever since. In the years around 2000 these alternatives were still being expressed in the debate between liberals and communitarians.

Emile Durkheim (1858–1917) developed Hegel's key question about the moral basis of modern societies in new directions. 'Modern society' is henceforth understood in terms of industrialization, division of labor, and democratization, processes that only had just begun when Hegel reflected on society, but were much more evident for Durkheim. His key question dealt with social solidarity, and how to bridge the distance between the state and the individual. The point of departure for Durkheim when he posed this question was the debate about the nature of the moral and political sciences. He was unsatisfied with the speculative character of political philosophy. He was convinced neither by the individualistic and utilitarian approach developed by Kant or in the classical political economy, nor by Hegel's holistic enlightenment–romantic and mystical view on community, where the societies had goals, which were above and beyond those of the individuals. Durkheim looked in his positivist and empiricist approach for a position between Kant and Hegel for a society that was rather different than theirs. This debate was the very foundational moment of the social sciences in the contemporary sense.

The motor of the new turn of the debate was what in the 1830s was identified as the social question. The spread of industrial capitalism, with contract-based property rights and wage labor, provoked new forms not only of property but also of poverty and proletarianization, which went beyond the curing capacity of the conventional tools of philanthropy and Christian charity. A systemic problem inherent in industrial capitalism was identified and a debate on what was labeled the social issue emerged. With the ever stronger class language of the working class the social question was in the 1870s transformed into the class question.

Durkheim emphasizes the role of religion in premodern societies, in which, beyond the family, no other functionally cohesive institution other than religion existed. Religion provided 'mechanical solidarity,' which functioned as a social cement. This mechanical solidarity can be related to Hobbes's understanding of society (and nature) as clockwork divinely created but then going by itself. Post-Renaissance rationalism and the imagery of mechanical solidarity through religious cohesion, in the shape of Hobbes and others takes on new meaning when in the second half of the nineteenth century it was faced with a truly mechanical universe, i.e., the advances of physics, the division of labor, automated production, etc. In modern societies the division of labor changed the preconditions for social cohesion. A need for coordination of functional relationships emerged. The societies had become ever more complex with growing divergence among individuals in their social orientation. Their interpretations of the world did not necessarily converge toward one collective will. The state was the key instrument for collective action when societies had developed a certain degree of complexity. The fiction of the state as the tool of social security emerged with a capacity to promote social integration through political and social reforms suggested by the social and political sciences. This was the social state much more differentiated and with more tasks than the earlier state which basically was a war machine and a Hobbesian instrument for domestic social peace. The state as the instrumental–rational forms of belonging was connected to the imagery of the nation unified by organic, cultural, and social bonds integrating both civic and ethnic dimensions. With this kind of reflection in the

wake of the growing social division of labor organic solidarity arose alongside mechanical solidarity.

A growing emphasis on ethnicity and a stronger demarcation to other nations accompanied the increasing social dimension of nationalism. It was not by coincidence that Bismarck's imagery of state socialism (below) went hand in hand with the martial German unification, welfare with warfare. The social conservatively oriented nationalism from the 1870s/1880s onwards was different from the earlier liberal nationalism with an emphasis on the civic dimension and with less interest in the demarcation between nations. Giuseppe Mazzini (1805–72), a protagonist of liberal nationalism and the founder of both Young Italy and Young Europe, did not see any problem in coexisting national projects peacefully united in an international order. Nationalism and cosmopolitan internationalism constituted one another.

The state as the functional answer to social differentiation and the problem of social disintegration in the wake of economic integration, and the imagery of the nation as the locus of social cohesion and community reinforced potentiating one another, although the final merger between state and nation in the modern nation states occurred only after 1945. Tensions emerged in multiethnic empires. One way to solve such tensions was reinforced nationalism at the imperial level under demarcation to other empires and underpinning the colonial extension of empires. The empires in struggle for survival (Charles Darwin (1809–82) and Herbert Spencer (1820–1903)) with other empires promoted social cohesion, and social imperialism. The nineteenth-century location of nation varied under more or less tension between a specific state and within a multinational empire which accommodated several nationalities.

Durkheim problematizes the mediation between the individual and the society in different directions and from different points of departure. The political philosophy of Enlightenment focused on concepts like people's sovereignty and political representation and on the issue of the institutional distribution of power. With intensified industrialization, capital concentration, the rise of the labor movement, and ideas of universal suffrage, the theoretical framework provided by the Enlightenment philosophers had become insufficient. New forms of relationships between the individual and the state levels had to be developed. In this context Durkheim evokes the notion of secondary institutions and develops ideas about what kind of organizational forms would fit an industrial society.

Taking his theoretical point of departure in his idea of division of labor as the basic principle of modern societies, he suggests interest-based representation through corporations rather than territory-based political representation. The corporations would reflect modern professions rather than traditional crafts and estates. In his functionalist approach Durkheim developed a moral theory in which he paid relatively little attention to questions of power and authority structures and social inequality. However his view on morality based on corporate representation and related to his idea of solidarity indicated the social question. The political function of the secondary institutions was both to keep the state sufficiently free from influences from the masses, so that the state could fulfill its role as the shaper of the society, and to protect the individuals from oppression by the state.

Karl Marx (1818–83) and Friedrich Engels (1820–95) followed a different route. In their historical materialism, and in their emphasis on the political role of the proletariat, they depreciated the concept of society ('bourgeois'). They reevaluated the community concept with its derivative communism, where socialism, with the same etymological origin as society, was seen as a transitional phase toward communism, the final stage, where history ceased. Marx and Engels criticized the view of society in earlier French and British social history, where society was seen as a set of mutual interactions. They criticized this view of society as being a society of exchange in which every member was a merchant. The society Marx and Engels discerned was societies in plural, where each of them was determined by the specific ways in which the production was organized. In each type of society specific power relationships prevailed. They followed one another in historical phases: the original society (*Urgesellschaft*), slave society, feudal society, bourgeois or capitalist society, socialist society, and communist community, where the merger into the old Greek *χοινωνί'α* was fulfilled in a new action- and future-oriented utopia.

Hegel's problematization of the leading idea in moral philosophy and political economy, that society was based on the individuals and their agreement on conventions, constituted in the German-speaking area a step in the development from the traditional to the critical theory of society (cf Ruda (2011) and Honneth (2011)). The critical thought was a core dimension of the enlightenment philosophy (Koselleck, 1989 [1959]). It became more pronounced through the debate on the social question and from the 1870s onwards to the class question. Karl Marx and Friedrich Engels were protagonists in the development of critical thought. Also positivism in the wake of Auguste Comte (1798–1857) and French cultural radicalism in the 1880s promoted the attention to criticism. These developments culminated in the critical theory established in the 1930s by Max Horkheimer (1895–1973), Theodor Adorno (1903–69) and their circle with a Marxist subtext but influenced also by Hegel and Freud (the Frankfurt school). Their long chain of critical thought introduced new basic concepts and distinguished between society and community, between society and state, and between *bürgerliche* (the German term connotes in English translation both 'bourgeois' and 'civil') society and society. This critical social theory must be seen in the context of the social revolutionary movement, which emerged in the nineteenth century. This movement could be seen as a response to the crisis, which since the French Revolution, and with the industrial revolution, marked the everyday experiences in Europe and gradually also beyond Europe. Critical theory was an alternative reflection on society and community with respect to Durkheim's, based on ideas of functional differentiation and division of labor.

Politically the most long-term important element of the tradition of critical thought was the conceptualization of a social history, or history of society, *Gesellschaftsgeschichte*, with explicit connection of historical processes to social theories, in particular those designed by Max Weber but partly also Karl Marx. Long before the French revolution German scholars had propagated a historical approach to political, constitutional, and legal questions under demarcation to the unhistorical rationalism of the French *philosophes*. Legal scholars insisted on the value of empirical 'positive law.' The

historical school argued that economic performance and social organization could not be conceptualized in universal categories but had to be understood in the framework of customs, legal norms, political institutions and practices, culture and the economic organization and practices of the production of subsistence and wealth, which all had emerged and grown historically, specific for each people. An academic key discipline in this development was law. Friedrich Carl von Savigny (1779–1861) and Carl Friedrich Eichhorn (1781–1854) developed the historical school where they emphasized the historical tradition as opposed to speculation in natural right philosophy. The focus was on the sources of law as they had emerged from the spirit of the people. The efforts of the historical school aimed at the reconstruction of a national past paralleling and reinforcing the movement toward political and legal unity of a unified German state.

The historicists put the classical economic theory in economics in the wake of Adam Smith under pressure. Already the 'older historical school' (Gustav Schmoller) with names like Wilhelm Roscher (1817–94), Bruno Hildebrand (1812–78), and Karl Knies (1821–98) had begun to undermine the classical theory with arguments about the historicity and contextuality of economic and social processes. Not abstract models or universal laws of how the economies functioned, but the historical experiences laid down in political, social and economic institutions, and widely varying from country to country, explained the functioning and the development of the economy in each specific case. This was the view that Friedrich Carl von Savigny had applied to legal interpretations, and which from there evolved a methodology in other academic disciplines, not the least political economy. The center of this academic movement against universalism was Germany. Karl Marx and Friedrich Engels tried to develop a historical universalism with a certain degree of openness toward historical variety.

The younger historical school with Gustav Schmoller (1838–1917) as uncontested protagonist gave the historicist approach greater cohesion and more punch. He confronted the axiomatic–deductive approach of classical economics. He was critical to what the economists in the classical tradition argued to be regularities and conformity to law in economic life. Their theory about rationally acting economic individuals led astray. Only the historical view on society and humans could provide interpretative power to developments and behavior.

The economists did not accept the criticism of Schmoller and the other historicists, but hit back. They were later to go under the label of the neoclassical school with their neoclassical theory. Schmoller called them the Austrian school to suggest provincialism in a disliking review of a book by Carl Menger (1840–1921) which attacked the methods of the historical school. The debate that followed came to become known as the *Methodenstreit*.

In the 1870s social sciences and social politics had become ever more intertwined in Germany, social political and social scientific intentions merged. After the violent unification of a German nation through Bismarck's wars with the neighboring countries the turn came to domestic national integration. Social sciences and social politics were effective instruments here. In 1872, a group of professors of political economy, *Nationalökonomie*, met to discuss how to promote state intervention in social issues on the basis of historical–economic investigations. In 1873, they founded the *Verein für Sozialpolitik*, the Association for Social Politics. The establishment of the professors' association for social politics stood in close connection to the foundation of the German *Reich* in 1871.

Supported by this academic trend, German Chancellor Otto von Bismarck's great political achievement was the appropriation of the national question from the liberals and the social question from the socialists making nationalism and ideas of a social state (*Sozialstaat*) conservative virtues.

The political intention of the association of economists was fully focusing on the state. Despite all socialist reproaches from classical laissez-faire-oriented economists, who referred to the members of the association as *Kathedersozialisten*, alluding to their academic chairs, a label which soon broke through in the public debate in Germany and abroad, the members of the association saw themselves in a mediating position between socialists and market apologetics. The task of the association was to become a forum in which academic, economic and political–administrative elites could communicate about necessary measures to be undertaken on the basis of social scientific research results. An urgent requirement was the establishment of a public debate, a *bürgerliche Öffentlichkiet*. The idea of social politics was based on the conscious insight that state and society necessarily had to be activated in order to establish a balance between the social interests drifting apart.

In France the development was similar although there the academic discipline was sociology, in particular in the version developed by Émile Durkheim. The development was somewhat later in the framework of the Third Republic. However, also in political theory there was a movement from the emphasis on neoclassical theory toward historically-cum-analytically derived theories for state intervention. In the *sciences morales et politiques*, too, efforts emerged to develop a political science aiming at supporting national action capacity in the social field, not least in the teaching for the cadres of the administrative elite.

A few years after the death of Karl Marx and after ever stronger experiences of industrial change and economic concentration, Ferdinand Tönnies (1855–1936), analyzed quite differently, but still with a utopian embedding of the community concept, the connection between *Gemeinschaft* and *Gesellschaft*. In his view community took on a social–romantic meaning connoting an archaic past based on the family and providing feelings of holism. His utopia was projected toward the past instead of the future. Society was the term used to describe the breaking-up of this past through industrialization, social disintegration, and experiences of atomism. Tönnies saw communism as a cultural system of community and socialism as the cultural system of society, i.e., communism was rather referred to as a historical or even archaic category, a kind of prototype, while socialism reflected the industrial society.

Tönnies' subordination of society to community had long-term political impact. Community was, in his view, in all sociological conceptualizations the superior and in all historical analyses the anterior concept. Community was the dialectical womb from which society arose in historical processes. The

concept of society described the law-bound normal process of the decline of all community: the same process that Marx and Engels – in accordance with Hegel's idealistic philosophy and their critical–normative prognosis, where society had become community – described as emancipation and a development toward higher stages of social organization, Tönnies analyzed as decay, as inexorable as the coming communism in the view of Marx and Engels. The only future hope that Tönnies could discern was weak: that the force of the community also within the era of society would remain although it was declining. The community could in his view be promoted through the cooperative movement and through the trade union and solidarity idea in the labor movement.

Although Tönnies' concept of society includes the totality of the relationships among the individuals mediated through exchange, and in this respect can be historically situated, this historical location involves conceptual distinctions which cannot be justified either in genetic or in linguistic–critical terms. Both Max Weber (1864–1920) and Georg Simmel (1858–1918) observed this inconsistency and tried to solve it through a paradigmatic change of the sociological terminology. To consider social institutions like state, church, the cooperative (*Genossenschaft*) as independent entities preceding the individual and attach them to a general society concept was in Weber's view a metaphysic residual, which needed to be overcome. He replaced society as a basic sociological concept with the term *Vergesellschaftung*, 'societalization,' an extremely general concept containing all forms of rationally motivated interest relationships under one umbrella concept. The generalization of the sociological conceptual framework around the term *Vergesellschaftung* certainly described processes and social change, but was basically ahistorical, where the analysis of the development was deprived of historical contextualization. *Ahistorical* here does not mean a lack of a chronological dimension but refers to the fact that the social dynamics was deeply teleological losing the openness and contingency of historical processes out of sight. Historical contexts were understood as 'cultural tragedy' (Simmel) or 'destiny of the rationalization of society through science' with total disenchantment as the final outcome of the *Vergesellschaftung* (Weber). The process of dehistorization of the concept of society that Tönnies began with his outline of a universal process, and Weber continued with his criticism of Tönnies, had the effect of drawing growing attention to the community concept. *Gemeinschaft*, which can be seen as a kind of pseudohistorization, had become topical. With the introduction of the concept of community in this way the sociological theory in Germany unintentionally opened up for the reactionary, opposition against the industrial society. While in other European languages society and community remained synonymous concepts – in the wake of the historical school and Durkheim, who had narrowed down the gap between these two concepts that the enlightenment philosophers had opened up – *Gemeinschaft* had become in Germany an ideological key concept connected to another highly ideologized crucial concept: the *Volk*. The ideological entanglement of the two concepts had become a national–conservative instrument to mobilize the *völkische* movement after World War I against socialism, capitalism, and industrialism.

The cult and the dogmatization of the *Gemeinschaft* concept were also confirmed in German philosophy at this time. Max Scheler (1874–1928) identified community as a person *sui generis*, 'a person of persons' as opposed to society, which was nothing but the sum of its individuals. He thus reinforced Tönnies' distinction. Community was based on blood, tradition, and historicity, while society was the waste product of internal disintegrative processes in the community. Society was synonymous with public, which continuously removed – Marx would have said alienated – the individual. Community was synonymous with personal solidarity, which reintegrated the individual. In Durkheimian terms this was a move from organic toward mechanical solidarity.

Already before World War II, Talcott Parsons (1902–79) developed a view where community and society were seen as key concepts in structural–functional alternatives of value orientation, 'pattern variables': affectivity versus affective neutrality, particularity versus universalism, ascription versus achievement, diffuseness versus specificity. His approach was one, where, like in the German debate, the two concepts were separated, but for the rest his contribution was very different from the German debate.

In the 1950s René König (1906–92) was one of the leading figures in the reconstruction of German sociology. He argued vehemently against Tönnies' dichotomy and use of the *Gemeinschaft* concept. He argued from his basically Durkheimian perspective for an empirically oriented sociology with bridges to the American functionalism, where Talcott Parsons was a leading figure, as a source of inspiration, and warned against any attempt to conceptualize society as a totality, which only would lead to speculation and dogmatism. Community in the German form of *Gemeinschaft* was in the 1950s rejected from the political and sociological vocabulary and society emerged instead in the 1960s as the key concept to describe and analyze the social organization.

At the same time as König in Germany warned against the *Gemeinschaft*, concept community had become the name of the European integration project in the 1950s. One of the key problems when this project was formulated was how to make Germany a strong ally in the Cold War and at the same time guarantee that the strength was controllable for its allies. The main architects of this design came, in particular, from the USA, the victor, but also from France, where the concern about the key problem for historical reasons was particularly great. There, *communauté*, for historical reasons, in the 1950s had a much more positive value charge than *Gemeinschaft* in Germany integrating Durkheim's organic solidarity based on functional division of labor. Moreover, the Communauté Européenne was a concept that bypassed the conceptual bias on state and state sovereignty in international relations theory and international law. In the form of the European Community in German translation, *Gemeinschaft* came back in as a political concept and an intellectual tool to promote the German incorporation in the West European Alliance in the Cold War, and which, therefore, was disconnected from its historical heritage in the German speech area. When European integration in the 1970s was exposed to strains, the idea of a European identity emerged connected to ideas of a supranational Europe. This intensification of the European Community concept was emphasized in the 1990s when community was changed for union. This European development can be understood as part of a modernization theory which was resurfacing with

a communitarian twist in the 1990s as the reverse side of the liberal post-Soviet coin: the economist globalization rhetoric about profit-maximizing individuals on global markets untied from suffocating social ties. The imagery of social individuals freed from social bounds created its counterimagery of individuals tied together in a European Union with a European identity. The homogenizing discourse on a European identity attempted to provide the glue to bind a European community together. Such a theory of social integration, which took for granted that cultural cohesion existed for national societies, and then simply transferred the idea of state – formation onto a supranational European level, built around the concept of European identity, missed the point that the nineteenth-century construction of the nations in Europe did not start from preexisting units but emerged slowly in a tough and often violent conflict around the social and the class issues. The nations were the outcomes of these conflicts, not the point of departure. The final compromise around the social conflict was the merger of the state and the nation in the nation-states after 1945. The problem in translating the national experiences since the 1830s into a European future, revealed in today's European crisis, is the lack of a social dimension in the European construct. A process of renationalization accompanies the financial crisis. The general theoretical framework of the problem of the tension between economic integration and social disintegration is the debate between libertarians and communitarians in social sciences since the 1970s, which debate, in turn, in a long historical view could be seen as continuity under transformation of the bicentenary debate between Kantians and Hegelians. A point of departure for this theoretical debate was John Rawls's (1921–2002) *A Theory of Justice* (1971). Erected in the tradition of contract theories and Kantian liberalism his theory bypassed the questions of political obligation and the welfare state through the idea of distributive rights in individualist terms. Utilitarian philosophers objected but in the long term the most substantive opposition to the neo-Kantian approach emerged from the 'communitarians.' The debate between the liberals and the communitarians had become one of the most important issues in political philosophy in the 1980s. Methodologically the communitarians argued that the premise of individualism such as the idea of free and rational choice is wrong or biased and neglects the social, cultural, and historical contexts in which individuals act. In order to understand individuals one must look at their communities and communal relationships. In a normative sense the communitarians argued that the premises of individualism give rise to morally unsatisfactory consequences. Alasdair MacIntyre (b. 1929) in *After Virtue* (1984) questioned the fundamental philosophical assumptions of liberalism. He and others questioned the claim of the priority of the right over the good and the image of the freely choosing individual. Political arrangements cannot be justified without reference to common purposes. Freedom flourished within social interdependence, not among free-floating individuals. However, the kind of community the communitarians drafted was one that often focused on the family, the tribe, or the neighborhood rather than on the nation, the state, or the class. The communitarian community is more than a mere association; it is a unity in which the individuals are members not in artificial or instrumental terms, but within its own intrinsic value. This is a view with similarities to Hegel's *Sittlichkeit* idea.

In the debate, communitarianism has been dismissed both as little more than a corrective to the excesses of liberalism and as a form of old-fashioned collectivism. In the framework of the former view approaches have emerged, which can be described as a merger between liberalism and communitarianism. Michael Walzer (b. 1935) sees communitarian thought as a permanently recurring corrective to liberalism (1983). Charles Taylor (b. 1931) is another leading name in this approach. Taylor and Walzer are often referred to as liberal communitarians. The theoretical debate moved from the thick communitarian critique of thin liberalism to positions that combine elements of both. This trend was nurtured not the least from legal theory where a strong recent 'republican' turn aspires to hold both communitarian ideals and democratic participation together. The law was seen as sustaining community and promoting the common good to be negotiated through participation in a polity where liberal rights guaranteed that bargaining is uncoerced. Also, the globalization discourse on the emergence of a globally rather than nationally organized economic order promoted the trend of closure between liberalism and communitarianism. The attempts to reestablish community, experienced as being lost to transnational globally operating forces, resulted in liberal politics of recognition of cultural alternatives in the name of multiculturalism, which, in turn, has become a concept with negative connotation in the wake of the expanding global migration, in addition to the originally positive value charge. Multiculturalism does not only mean respect of cultural difference, but also acceptance of social inequalities. The historical search for a concept that unifies individual freedom and social solidarity continues.

Community Care in England

Caroline Glendinning, University of York, Heslington, York, UK

Abstract

Community care is a favored way of supporting disabled and older people in many countries. Arrangements for funding and delivering community – i.e., noninstitutional – services vary between countries and welfare regimes. This article focuses on the development of community care policies and practice over two decades in England. Nevertheless, the themes shaping community care in England – particularly the growing emphases on markets and service user choice – are very similar to priorities in many other countries. Over the past three decades, there have been marked shifts away from hospital-based and institutional care for disabled and older people, toward increased provision of intensive support for people in their own homes. These changes have been accompanied by the wholesale marketization of community care services, with first local authorities and later service users themselves increasingly purchasing publicly funded care from private provider organizations or privately employed care workers. Additionally, a range of policy and practice measures have aimed to improve the efficiency of community care services, especially at their interfaces with acute health care. However, the effectiveness of all these policies is seriously threatened by a severe lack of funding for community care services, relative to both current and projected future demand.

Introduction

This article documents the development of, and current debates in, community care services in England. Similar policy goals exist in many other countries, although the specific arrangements for funding and delivering community-based services vary between welfare regimes. While this article focuses on England, the measures described – particularly the introduction and development of quasi-markets, the increasing emphases on consumer choice and personalization, and measures to improve the efficiency and effectiveness of services – are of international relevance. Unlike some other countries, however, continuing failure to introduce radical reforms in the critically important area of funding may restrict the potential impacts of these measures.

The article first outlines the structure of English community care services. It then describes the simultaneous introduction of community care policies and quasi-markets and the subsequent developments in those quasi-markets aimed at increasing the consumer power of service users. The implications for the social care workforce and selected measures intended to improve the efficiency of community care services are summarized. The article concludes by highlighting the problem of securing adequate funding for community care services and the limitations of successive reform attempts.

Structure and Scope of Community Care

'Community care' denotes services and support for older and disabled people provided outside institutional settings such as residential homes and hospitals. It includes the very substantial unpaid support provided by close family members.

Responsibilities in England are fragmented between the separate budgets, structures, and cultures of the National Health Service (NHS), local authorities, and the Department for Work and Pensions (DWP), as follows (Glendinning, 2007):

- Help with personal and domestic care, day care, and other daytime activities are the responsibility of local authorities. Local authorities rarely provide these services themselves. Rather, their role is to fund and commission services from for-profit enterprises, charities, and social enterprises. Local authority funding comes from taxation and user charges. Local authorities also have statutory duties to assess the needs of family carers and provide help for carers, mostly as one-off grants or respite care. Local authorities are additionally responsible for funding housing-based support services, particularly for people with learning disabilities or mental health problems. There is currently interest in developing special housing with high-level support services on the premises as an alternative to residential care for older people.
- The NHS provides nursing and therapy services for people living in their own homes. NHS services are funded from general taxation and free of charge.
- Older and working-age disabled people needing regular or substantial help with personal care or supervision may be eligible for cash benefits to meet extra disability costs. Family carers may also claim Carers Allowance, which is intended to replace earnings lost because of care responsibilities. These benefits are the responsibility of the DWP.

Access to public resources for community care support can involve multiple assessments including income and assets/wealth tests; health and treatment needs; capacity for self-care and risks of harm; and other individual circumstances, especially the availability of family carers. These arrangements lack strategic coherence, are not easily understood, may be poorly targeted at those with highest needs (Wanless, 2006), and involve costly duplication. In addition, around 6 million family carers contribute care equivalent to £87 billion a year (Carers UK, 2007). These arrangements date from the late 1940s when responsibilities for the 'treatment' and 'cure' of 'sick' people were assigned to the newly established NHS, with local authorities providing personal and practical support for those needing 'care and attention' (Means and Smith, 1998). However, the boundaries between NHS and local authority responsibilities have shifted markedly over time (Lewis, 2001), so that people considered to need 'care and attention' now include those with severe cognitive

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28017-3

impairments, who are bedbound, or are terminally ill (Means and Smith, 1998).

During the past two decades, funding constraints have increasingly restricted local authority-funded support to those with the highest levels of need. Reflecting continuing policies to move care from residential to community settings, there was a 1% shift in expenditure from residential to community services over each of the years from 2002/3 to 2005/7. The numbers using short-term, intensive intermediate care services (see below) following hospital discharge rose from 98 000 to 225 000 during that period, but there was a 22% reduction in numbers of households receiving less intensive community-based support. In 2009, an estimated 6000 older people had high support needs but received no formal services or informal care and 1.5 million people had some shortfall in their care needs, if they lacked family care to make up the deficit (House of Commons Health Committee, 2010: p. 41).

Community Care Policies and the Introduction of Quasi-Markets

Until the 1980s, English local authorities were both funders and providers of domiciliary, residential, and day care services. However, reforms to means-tested benefits in 1980 made it easier for low-income older and disabled people to obtain social assistance funding for private residential and nursing home care. The impact was dramatic. Local authorities quickly saw the opportunity to shift responsibilities for funding institutional care onto the social assistance budget. At the same time, the NHS was closing long-stay learning disability, mental illness, and old age hospital facilities; again, social assistance funding for community-based residential care was an attractive option (Lewis and Glennerster, 1996).

The consequences were an exponential increase in public spending on institutional care; the rapid growth of privately owned residential and nursing homes; and major disincentives to local authorities to develop community-based services. Between 1986 and 1991, social assistance spending on residential and nursing homes rose from £10 million to over £2000 million , as a substantial private care market developed. However, this was contrary to the stated policy of community care. Following a critical Audit Commission (1986) report, a Committee of Enquiry (Department of Health and Social Security, 1988) recommended that responsibility for assessing needs and funding social care services should rest clearly with local authorities and that choice, flexibility, innovation, and quality should be stimulated through a 'mixed economy' in which public, private, and voluntary providers would compete on equal footings for public funding (Lewis and Glennerster, 1996; Means et al., 2002). Individual assessments and micropurchasing of flexible care 'packages' would be done by local authority 'care managers.'

These recommendations were implemented in 1993. Local authorities were encouraged increasingly to purchase services from charitable and for-profit providers, with whom their own in-house services now competed. Social workers became care managers, responsible for assessing needs and purchasing care from those providers with whom the local authority had contracts (Means et al., 2003). Market and consumer choices were effectively exercised by care managers on behalf of service users.

These reforms were largely successful in shifting funding from residential to community-based services and in stimulating new providers. In 1992, the private sector supplied only 2% of all domiciliary care (home help) contact hours; by 2001 this had increased to 60%. By 2001, 85% of all residential care places for adults were provided by private organizations, although this was no longer an expanding market as increasing demand for domiciliary services, falling occupancy rates, and other economic pressures squeezed the sector (Means et al., 2003). The numbers of homes and places within them subsequently dropped (although average home size has increased) (CSCI, 2009).

The Rise of Consumerism and Individualization in Community Care

During the 1980s, organizations of working-age physically disabled people campaigned to receive their community care support in the form of cash payments rather than services in kind, so they could employ their own care workers (personal assistants) to provide help with activities of their choosing, at times and in ways that best suited them (Morris, 2006). Legislation allowing local authority adult services departments to make cash direct payments instead of services in kind was introduced in 1997 for working-age disabled people and, from 2000, to people aged 65+ years, parents of disabled children, carers, and disabled young people (Glasby and Littlechild, 2006).

However, relatively few people chose direct payments, while take-up remained stubbornly low and highly variable between older and younger disabled people and between localities. Barriers to take-up included a lack of support services to help manage direct payments, anxieties among older and disabled people about managing direct payments, shortages of people willing to be employed as personal assistants, and professional resistance by care managers anxious about threats to traditional social work practice (Ellis, 2007; Fernández et al., 2007). Despite intensive policy pressures to encourage the direct payment option, by 2009 still only 9.5% of working-age adults and 3.6% of older people using community care services had direct payments (Care Quality Commission, 2011).

However, from around 2000, a new choice-based consumerist discourse began to shape community care policies. This intensified earlier trajectories of squeezing provider and professional interests, increasing user control and transforming community care markets:

> By putting users at the heart of services, enabling them to become participants in the design and delivery, services will be more effective by mobilizing millions of people as the co-producers of the public goods they value…(Leadbeater, 2004: pp. 19–20).

Consumerism aimed to expand the marketization of community care by devolving purchasing power to individual service users themselves, thereby giving them command over the public resources allocated to fund their community care

services. This also involved transfers of risk, from the state to the private sector and to service users. "Choice has been put forward in a wider range of different services and processes…many of which are potentially liberating for service users but some of which raise concerns about risk, capacity and equity" (Needham, 2007: pp. 74–75).

Leading the implementation of this new approach was a social enterprise organization *In Control* that worked initially with learning-disabled adults to give them a bigger role in assessing the support they need and deciding how resources for that support – termed personal budgets (PBs) – would be used. Direct payments had generally been used for employing personal assistants to provide personal and domestic care, whereas *In Control* encouraged much greater flexibility in the use of PBs, including purchasing mainstream services such as art classes or gym membership rather than attending a special day center. *In Control* connected closely with the principles underpinning direct payments, but had broader aims of 'redesigning' community care toward 'self-directed support' (Duffy, 2004).

In Control successfully promoted this approach in many English local authorities and the experience was picked up in three major policy statements (Prime Minister's Strategy Unit, 2005; HM Government, 2005; Department of Health, 2005), all of which proposed the piloting of individual budgets (IBs). Unlike *In Control*, IBs were to bring together funding from several government departments and services including community care, housing-related support, equipment, and adaptations. The intention was to avoid duplicate assessments and to increase choice, control, and flexibility for community care service users in using the full range of resources to which they were entitled, in line with agreed individual priorities and preferences. Like *In Control*, IBs could be used for conventional community care services, employing personal assistants, paying relatives and friends, or buying mainstream goods and services.

IBs were piloted in 13 English local authorities and subject to rigorous evaluation (Glendinning et al., 2008). IBs were generally welcomed by users as allowing more choice and control over daily activities. However, older IB users reported lower psychological well-being compared to those receiving conventional services, lower satisfaction than younger IB holders, and there was no evidence of cost-effectiveness for older people (Moran et al., 2012). Staff involved in piloting IBs encountered many challenges, including establishing processes for estimating the size of IBs and legitimate boundaries for what IBs could be spent on. Attempts to integrate resources from different government departments were largely unsuccessful, because of central legal, regulatory, and accountability barriers (Moran et al., 2011).

Before the IB pilots ended, a 3-year 'transformation' program was announced involving the extension of PBs to everyone eligible for community care (Department of Health, 2008). Significantly, PBs involved only community care resources – the ambitions of integrating funding streams and reducing multiple assessments had been abandoned. All adults eligible for community care were to be given PBs within 3 years. To support this, local authorities have had to transform methods for allocating funding to individuals and managing financial and other risks, help local provider markets adapt to demands from PB holders for new services, and provide information and support to help people plan and manage their budgets. Again progress has been slow; by March 2012, just over half of all adults potentially eligible for a PB had one in place (ADASS, 2012).

The Implications for the Social Care Workforce

The introduction of direct payments and extension of PBs has implications for the social care workforce, although these are contested. New opportunities for community care users to manage their own support have been argued to undermine the case for professional social work (Leece and Leece, 2011). Others have heralded a new social work role of 'care brokers,' helping people to identify, organize, and manage their community care support (Scourfield, 2008). New tensions in professional social work roles have also been identified, for example, between promoting autonomy and protection and between prevention and rationing (Lymbery and Postle, 2010; Lymbery, 2012).

At the front line, PBs may prompt a more diverse and casualized community care workforce. By 2010, an estimated 200 000 personal assistants were employed by older PB holders (Skills for Care, 2010). The requirement that PB holders be responsible for ensuring the national insurance contributions and taxes of their personal assistants are paid gives relationships between service users and personal assistants a quasi-contractual basis (Dominelli, 2009). However, there are no requirements for PB holders to provide formal contracts or conditions of employment, nor for personal assistants to have minimum qualifications (Skills for Care, 2008).

Surveys of PB holders report greater reliability and flexibility and fewer experiences of abuse by directly employed personal assistants than from workers from private home care agencies. Personal assistants also report high job satisfaction, albeit with complaints about long hours or low pay. Local authorities are developing systems to help PB holders manage their employment responsibilities, but these are highly variable between localities (CSCI, 2008).

Improving Efficiency in Community Care

Other reforms have aimed to improve the delivery, efficiency, and cost-effectiveness of community care services. Two initiatives are described here: intersectoral collaboration and reablement.

Intersectoral Collaboration

Barriers between health and social care services have long been identified as problematic, particularly at the interface with acute hospital care and in demedicalizing support for people with learning disabilities or mental health problems. Attempts to overcome these are equally long standing (Means and Smith, 1998; Means et al., 2002) but new incentives and other measures were introduced from the late 1990s, including legal obligations on NHS organizations and local authorities to work in partnership and national service frameworks that set benchmarks across both sectors (see Glendinning et al., 2005).

Many joint service developments have resulted, particularly in community care services for older people and those with mental health problems. Pooled budgets, joint strategic needs assessments, and joint service commissioning between local authorities and local NHS services have become widespread. Recently, some resources have been transferred from NHS budgets for community care services, with the requirement that these are used in partnership to promote integrated services.

Despite the less than compelling evidence of the cost-effectiveness of collaborative service developments (Cameron et al., 2012), there is apparently still a strong belief in the potential efficiency gains. However, other policies, such as the piloting of IBs (Glendinning et al., 2011), and structural reorganizations of English NHS services, continue to undermine collaboration between health and social care. Moreover, the focus on this particular service intersection may itself inhibit collaborative activities across a wider range of community-based services (Newman et al., 2008).

Reablement

Since 2000, a range of intermediate care and reablement services have been introduced with the aims of improving the efficiency of acute hospitals, promoting independence and avoiding longer term service use, particularly among older people. They include short-term, intensive services to prevent hospital admission and support early hospital discharge (Department of Health, 2000; Godfrey et al., 2005). These are complemented by short-term home care reablement services that help people (re)acquire confidence and daily living skills at home following illness or surgery. Reablement services are often jointly funded by the NHS and local authorities; occupational therapist involvement and rapid access to equipment and assistive technology are vital elements of reablement (Glendinning et al., 2010).

Home care reablement has been found to reduce significantly the subsequent use of community care services, compared to people using conventional home care services, although some of this reduction is offset by the higher cost of the reablement intervention. Nevertheless, it is likely to be cost-effective because of the marked improvements in outcomes for users (Glendinning et al., 2010).

Overall Impacts on Efficiency

There have been concerns that these developments – particularly the growth of reablement services – have been driven primarily by the imperative of increasing efficiency in the acute hospital sector, rather than improving community care services and outcomes. Of increasing concern, however, is the extensive underfunding of community care services relative to need, increasing demographic pressures and changing patterns of morbidity. For example, around a third of the NHS resources recently allocated for partnership working and integrated services are being used to offset cuts in local authority budgets (Humphries, 2013). Similarly, the efficiency of home care reablement services is reduced if users cannot be discharged promptly because of inadequate funding and capacity in the standard home care services that provide longer term support (Glendinning et al., 2010). Moreover, reablement services demonstrate the greatest benefits for people with primarily physical health problems and are likely to be less effective for the growing numbers of people with multiple chronic health problems and dementia.

Since the mid-1990s, funding constraints have led local authorities to restrict eligibility for publicly funded community care services to those with the highest level needs and lowest income levels. Since 2010, there has been a 14% overall drop in the numbers of people receiving publicly funded community care, a trend that began in 2008 and is even steeper among older people. Three main consequences are evident. First, there is growing concern about the lack of support for people with lower level needs – those needing help with shopping, social activities outside the home, gardening, and cleaning – amid arguments that such support can have important preventive functions and delay needs for more intensive, crisis intervention services (ADASS/LGA, 2003; Audit Commission, 2000). Second, rising eligibility thresholds have led to burgeoning numbers of people funding their own community care services – around 270 000 older people according to one estimate (IPC, 2012). There is no evidence on the quality or effectiveness of the service choices they make. Third, there has been a 26% increase in the numbers of people providing substantial amounts of unpaid care to relatives and friends over the past decade (Carers UK, 2012). Substantial unpaid care-giving responsibilities that force carers to leave paid work have wider economic effects. Other extrinsic factors, including changes in local governance and reforms in other welfare sectors (Newman et al., 2008) also affect the success of efficiency-promoting initiatives and the optimization of outcomes and cost-effectiveness of community care services.

Funding and Fairness

Fragmented policy and funding responsibilities for community care are partly to blame for the long history of attempts to reform funding. There is widespread dissatisfaction with current arrangements, although public understanding is poor:

> It often comes as an unwelcome surprise to older people to discover that social care is means-tested and they are expected to rely on their own savings and income until their assets have fallen to the threshold set for state-funded care. It is a common complaint that the existing system penalizes those who have saved for their own old age. (Wanless, 2006: p. xxi)

Since 1996, there have been numerous proposals, from within and outside government, for funding reforms that would safeguard eligibility, increase fairness, and reduce local variations in access to and levels of community care services (Humphries, 2013).

The most recent proposals (Department of Health, 2011) primarily address the very high costs that can be incurred by a minority of people who spend extended periods in residential care. Implementation of these proposals from 2016 will limit total individual spending on care costs to £72 000 (HM Treasury, 2013). In principle, this introduces protection from the catastrophic costs of community care services similar to the protection offered by the NHS in

relation to catastrophic health care costs (Humphries, 2013). Implementation should also be accompanied by widespread access to information, advice, and assessment for community care, for older people, disabled people, and family carers, again extending the principle of universality. An additional 100 000 older people are expected to receive some public funding toward their care costs. Disabled young adults will be entitled to free community care support; those who become disabled between age 18 and 65 years will have a lower cap on their total personal spending. The reforms will mainly benefit younger disabled adults, and older people with relatively high care needs and modest incomes/assets, but are nevertheless broadly progressive (Humphries, 2013).

Although the reforms have been widely welcomed, they expose some major limitations. First, proposals for calculating which costs should count toward the £72 000 cap are far from transparent (Department of Health, 2013). There is huge potential for misunderstanding, disagreement, and error. Even more significant is the continuing failure to address the wider lack of funding for community care services and the structural fragmentation of current arrangements. Between 2005/06 and 2010/11, demand for social care by older people outstripped expenditure by around 9%. Recent cuts in public spending will reduce English local authority budgets for community care services by almost £2 billion between 2011 and 2013 (Community Care, 2013). For the future, continuing demographic pressures will increase the numbers of older people with significant care needs by 600 000 by 2030. The numbers of younger adults with learning disabilities are also expected to rise by one-third and those with physical or sensory disabilities by 7.5% during the same period (Humphries, 2013). An additional £8.3 billion will be needed by 2025, just to maintain local authority spending on older people's community care support at current levels.

Conclusions

Since 1990, the coverage of publicly funded community care services in England has contracted significantly. Intensive domiciliary services are provided only to those with the highest levels of need; many people are excluded altogether because of high eligibility thresholds, modest assets and/or incomes, and/or high levels of family support. With the introduction of quasi-markets, community care services have become more fragmented and this has increased with the introduction of PBs.

Underpinning these trends is the continuing challenge of finding a politically acceptable way of driving more money into community care services:

> The problems, and the options, for solving funding reform, have long been known; and prime opportunities to initiate reform … have been squandered. The failure to grasp this nettle is sadly indicative of the low priority given to social care by successive administrations. (House of Commons Health Committee, 2010: p. 67)

This political challenge is heightened by a highly complex and fragmented system, with separate central government responsibilities, funding streams, and local service delivery arrangements. Radical reforms therefore raise challenging constitutional issues. Nevertheless, unless more funding is made available, fewer and fewer people will be eligible for publicly funded community care. More people will consequently be exposed to catastrophic costs as they spend down their assets on privately purchased residential or intensive community care; and family carers will carry increasingly unsupportable burdens.

Against this background, the priority given to introducing quasi-markets and their extension to individualized funding through PBs is remarkable. But this could be of relatively little importance if increasing numbers of disabled and older people are assessed as ineligible for publicly funded community care services by continuing high eligibility thresholds. The marketization reforms have not injected further resources into community care services but simply altered the ways in which existing, limited resources are allocated and used. Moreover, neither direct payments nor PBs may succeed in delivering improved outcomes for the majority of community care service users. Both initiatives take a method of deploying resources that appears to work well for some community care service users (working-age physically disabled people and those with learning disabilities, respectively) and universalize this to all users, including frail and cognitively impaired older people. There remain significant questions as to whether the benefits of individualized funding and consumer choice outweigh the potential increases in responsibilities and risks for community care service users.

Community Genetics

Leo Pieter ten Kate, VU University Medical Center, Amsterdam, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Community genetics was defined by an international group of authors in 2010 as "the art and science of the responsible and realistic application of health and disease-related genetics and genomics knowledge and technologies in human populations and communities to the benefit of the individuals therein. Community genetics is multi-, inter- and transdisciplinary and aims at maximizing benefits while minimizing the risk of harm, respecting the autonomy of individuals and ensuring equity."

Activities and areas of interest include genetic screening, genetic literacy and education, access and quality of genetic services, genetics in primary care, genetics in low- and middle-income countries, genetics in disadvantaged subpopulations, registries of congenital and genetic disorders, genetics in preconception care, public consultation about genetic issues, and epidemiological, economic, psychosocial, ethical, legal, and policy issues.

Community genetics was first mentioned in the scientific literature in 1975. The international scientific journal *Community Genetics* was published by Karger in the period 1998–2008 and was succeeded by the *Journal of Community Genetics*, published by Springer, since 2010.

The international multidisciplinary community genetics network was founded in 2007. At the time of writing the network had 1058 members residing in 74 different countries.

Introduction

The term 'community genetics' has different meanings in medicine and biology. In biology, it refers to the study of evolutionary processes of interacting populations of organisms in a circumscribed location, while in the field of medicine, it refers to the application of genetics to the study and service of humans in a given community. Although communities may be defined by location (such as the inhabitants of a village, town, or country), they may also be defined by history (migrants from one country to another or specific ethnic groups within a country), or by a common problem (e.g., all carriers of a certain recessive gene in a certain population), and also on the basis of interaction with another organism (such as the malaria parasite).

Origin and Further Evolution

The earliest known use of the term 'community genetics' was found in a paper describing the cytogenetic observations in a genetic clinic servicing the community of Tulsa, Oklahoma (Coldwell et al., 1975). Apparently independent of this early use, the term 'community genetics services' was adopted by WHO in the 1980s, and a more comprehensive view on community genetics was given by Bernadette Modell in a paper in 1992 (ten Kate et al., 2010). As mentioned by Modell and Kuliev (1998), many individuals had already devoted a large part of their lives to applying genetic approaches at the community level long before the term was invented.

A dedicated journal, called *Community Genetics*, was published by the publisher Karger AG, from 1998 till 2008, after which its title was changed to *Public Health Genomics*. Another title, the *Journal of Community Genetics* was published by Springer from 2010 onward. A multidisciplinary international e-mail network with its own newsletter was started in 2007 (ten Kate and Plourde, 2011) and has 1057 members at the time of writing.

Definition

There have been several definitions of community genetics in the past. The most recent definition was drafted by a group of 14 authors from five continents (ten Kate et al., 2010).

Community genetics is the art and science of the responsible and realistic application of health and disease-related genetics and genomics knowledge and technologies in human populations and communities to the benefit of the individuals therein. Community genetics is multi-, inter-, and transdisciplinary and aims at maximizing benefits while minimizing the risk of harm, respecting the autonomy of individuals and ensuring equity.

Activities and Areas of Interest

While a definition may give some impression of what the field of community genetics is about, an overview of activities and other interests under this umbrella may help to make things more vivid.

Genetic Screening

Genetic screening is perhaps the most typical example of a community genetics activity. It is an offer of genetic testing to all persons within a community, or it is targeted to a subset of those people, such as newborns, or pregnant women. It is not restricted to those with a disease or a high risk of developing it as is the case with genetic testing in a clinical setting. A more extensive discussion of this issue can be found elsewhere in this encyclopedia. A recent paper by Kingsmore et al. (2012) on

genetic screening by next-generation sequencing in low- and middle-income (LMI) countries provides food for thought.

Genetic Literacy and Education

Genetic literacy of professionals, public, and policymakers facilitates the introduction of community genetic services and empowers the members of the community to make informed decisions on all matters of genetics arising. As scientific developments in genetics are moving fast and steadily, and as misconceptions about genetics are frequent, there is a need for permanent attention for genetics education for all three target groups.

Access and Quality of Genetic Services

Easy and equal access to high-quality genetic services for members of the population is a prerequisite for offering genetic screening and genetics education. Such services are commonly organized at clinical genetic centers where individuals and families can find genetic diagnosis and counseling for genetic disorders in affected persons in their families. Genetic diagnosis includes taking a thorough family history, syndromology, cytogenetics, DNA testing, prenatal diagnosis, and sometimes also preimplantation genetic diagnosis.

Genetics in Primary Care

Primary care is in a special position to act as a first observer, contact, and an advisor regarding genetic disorders and risks in the population under their surveillance. It is therefore important that primary care is empowered to perform these tasks.

Genetics in LMI Countries

There is a special need for community genetics services in countries where there are limited resources and availability of genetic services. WHO has repeatedly emphasized the importance of community genetics services in LMI countries (WHO, 2010).

Genetics in Disadvantaged Subpopulations

In every country, there are subpopulations that are disadvantaged by, for instance, socioeconomical status, infrastructure, cultural isolation, and educational gaps. Some of these subpopulations are also at special genetic risk. An example is the higher prevalence of sickle-cell anemia among immigrants of African descent in Western countries. Disadvantaged subpopulations need extra attention to ensure that they can benefit from genetic services as well as those who are in a better position.

Registries of Genetic/Congenital Disorders

Registries of genetic and/or congenital disorders contain data on large numbers of persons from defined communities and are of great value for needs assessment, surveillance, and research.

Genetics in Preconception Care

Preconception care offers the possibility to provide a better start of the embryo at conception or in the first weeks of prenatal life. Providing information on many factors like lifestyle, chronic diseases, medication, infectious diseases, and folic acid supplementation may prevent serious consequences for mother and child. Genetic counseling before conception increases the array of reproductive choices for the parents with genetic disorders or with genetic disorders in their families, and in case of consanguinity. 'Genetic aspects of preconception consultation in primary care' was the subject of a special issue of the *Journal of Community Genetics* in 2012 (Special issue, 2012).

Public Consultation about Genetic Issues

There are several examples of community genetics activities based on initiatives by people outside the medical or genetic community. Conversely, it is always advisable to consult the public, opinion makers, and authorities before embarking on a new initiative. There are many ways to do this, for example, by focus groups, surveys, or media discussions.

Epidemiologic Issues

Since gene frequencies and prevalences of genetic diseases differ between populations and also by population substructure, knowledge of these parameters is indispensable for planning and follow-up.

Psychosocial Issues

Psychosocial issues are very important, both when people are developing (or are at risk of developing) a severe disease in themselves or a close family member (e.g., hereditary breast cancer), and when they are confronted pre- or postnatally with a serious disorder (or a risk of such a disorder) in their child and have to choose between two evils like termination of a pregnancy and continuation of a pregnancy that will result in a life full of suffering for their child.

Ethical and Legal Issues

Ethical issues are manifold in this field. Their importance is illustrated by the amount of space devoted to ethical issues in the definition of community genetics: Community genetics aims at maximizing benefits while minimizing the risk of harm, respecting the autonomy of individuals and ensuring equity.

Next generation sequencing will increase the number of occasions in which ethical issues arise, as this procedure results in finding many more mutations in the individual than testing single genes does. While this problem has been discussed already in relation to research findings (Bredenoord et al., 2011), discussion will spread to clinical and community genetics as well (Kingsmore et al., 2012). For instance when offering next generation carrier screening to couples who want to have children, one question to be answered is what to do when for instance a mutation predisposing to a dominant disease is found. This should be discussed during prescreening counseling, but are we able to inform participants adequately about the many possible unsolicited findings?

Legal issues are of course also very important, but as legal situations tend to differ per country or larger region, they should be discussed at the country or regional level.

Economic Issues and Policy Issues

The first questions asked by health decision makers usually concern costs (Modell and Kuliev, 1998). If the costs of treatment of a large number of patients with for instance thalassemia greatly exceed national resources, a screening program to find and alert carrier couples may be justifiable as long as informed choice of carrier couples is guaranteed. In other cases, that is, where national resources are not overstretched, costs of services, as well as costs of absence of services still have to be presented as part of a rational decision-making process.

Delineation

In this section, we will make some remarks regarding differences between community genetics and some other related fields.

Clinical Genetics

Clinical genetics focuses on patients and families with genetic disorders. It is basically a reactive specialty, with some proactive elements. Establishing a diagnosis and providing genetic counseling may be followed by the offer of genetic testing in healthy family members if appropriate. Community genetics is basically proactive since members of the population are approached without prior knowledge of their personal or family history.

Population Genetics/Genomics and Genetic Epidemiology

Population genetics/genomics and genetic epidemiology study the fate of genes and genomes in populations and families, and so provide basic knowledge and understanding useful for community genetics. In the absence of a service component, they do not constitute a type of community genetics on their own.

Public Health Genetics and Genomics

The aim of public health is to prevent disease and improve health. Public health measures are judged by the amount of success achieved in reaching these goals. Preventing disease by eliminating the patient or the individual at risk is, however, a perverted view of prevention. Although employing genetic or genomic technology is acceptable in preventing common diseases occurring late in life in those already born, problems arise when public health approaches stressing prevention are used when it concerns the unborn. Although the majority of respondents in a study of public attitudes toward the introduction of noninvasive prenatal diagnosis described their first response as positive, especially with regard to the individual/medical rationale, they expressed unease concerning public health rationale and societal implications (Kelly and Farrimond, 2012). Community genetics, with its emphasis on the individual and on informed choice, does not carry the odium of public health prevention goal (ten Kate, 2005).

The Community Genetics Network

An international multidisciplinary e-mail network of researchers and others interested in community genetics was started in 2007. Members receive a newsletter with references to papers in the field of community genetics written by the members, a list of upcoming courses and conferences, and messages from members to the other members. The newsletter appeared originally once a month, but now appears twice a month. The appearance of the 50th newsletter in 2010 gave cause to compile a report on the first 3 years of the network, which connected 858 members in 70 countries at that time (ten Kate and Plourde, 2011).

At the time of writing, there are 1058 members in 74 countries. Four hundred and five members reside in the Americas (9 countries), 399 in Europe (30 countries), 147 in Asia (26 countries), 74 in Australia and New Zealand (2 countries), and 33 in Africa (7 countries). The five countries with the largest numbers of members are the United States (298 members), the United Kingdom (127 members), the Netherlands (105 members), Canada (81 members), and Australia (69 members).

The steady growth of the membership is based on invitations to authors of scientific papers on subjects in the field of community genetics on the one end and on spontaneous applications to commgennet@gmail.com by persons who express their interest in the network and newsletter on the other. Membership is free of charge. The multidisciplinary character of community genetics is evident from an alphabetical listing of 20 different disciplines in a small sample of the members: biochemistry, biostatistics, clinical genetics, epidemiology, ethics, genetic counseling, hematology, medical genetics, molecular genetics, nursing, obstetrics, ophthalmology, patient advocacy, pediatrics, pharmacogenetics, psychiatry, psychology, public health, and sociology.

When invited to indicate their interests from a list of possible issues, 51% of members highlighted genetic screening. Ethical and psychosocial issues were each mentioned by 29%, genetic education and legal issues by 28% and 27%, respectively. Interest in epidemiology scored 21%. Access to genetic services and genetics in primary care was mentioned by 18% and 17%, respectively. Lower scores were found for genetic registries, genetics of disadvantaged population, public consultation, and economic issues in decreasing order of adherence.

An analysis of the 1489 papers of members mentioned in the 50 newsletters in the first 3 years of existence of the network gives another indication of the diversity of its members. References to papers of the members are only included in the newsletter if the papers are written in English, are listed in PubMed, and appeared no longer ago than 3 months before publication of the newsletter. The 1489 papers were published in 485 different journals, of which 278 (57%) published only one of these papers (ten Kate and Plourde, 2011).

Membership of the community genetics network is free of charge. Those interested should send an e-mail to commgennet@gmail.com for information.

Discussion

Reporting on what has been achieved so far is an easy task compared to predicting future developments. Nevertheless, at this point in time we can be sure that new diagnostic methods like next-generation sequencing and noninvasive prenatal diagnosis will increase the application of genetic and genomic knowledge on a large scale in human populations and communities to the benefit of the individuals therein.

Abstract

Resilience has become a common word in aiming to articulate how communities should deal with disaster. Both 'resilience' and 'community' are contested through multiple definitions. Different understandings are explored through four artificial and overlapping hazard categories: (1) natural (or environment) hazards; (2) technological hazards; (3) violent social crisis such as terrorism and violent crime; and (4) nonviolent social crisis. The most encompassing and successful approaches for community resilience to disasters involve full participation of all community members in having access to resources and choices for helping themselves deal with day-to-day and longer term challenges.

Introduction

How do communities get through disaster? A common word these days is 'resilience,' so that much of the work in dealing with disasters aims for 'resilience building.' Definitions and conceptualizations of resilience vary, with different disciplines and traditions viewing the term and its application differently. Additionally, the answers to the questions 'resilience by what?' and 'resilience to what?' can be different. Psychologists might focus on the resilience of individuals to external influences. Engineers might highlight the resilience of a building to a force. Here, we focus on 'community resilience to disasters,' considering all forms of disaster across various scales. We start by considering how individuals react to personal calamity, which they might experience.

A loved one dies suddenly. You receive the call no one wants. What you experienced as 'normal' life then stops, pausing for a time. You are unfocused, depressed, and perhaps angry. You do not function as you usually do at work, in the home, on the street, or interacting with people. Your interpretation of the meaning of life is affected, perhaps profoundly through a tsunami of emotion or only weakened as a chimney after a small earthquake (Aloudat and Christensen, 2012: 570–572).

Most often you 'bounce back.' You recover from the disaster and the changes to your worldview. You begin to function as you did before. Your sense of meaning, hope, and expectations are restored. Friendship, love, and solidarity have helped you, as have rituals of remembrance. It takes time, but you celebrate the loved one's life and can turn that life, your contribution to it, and your memories around in your hands like a precious vase or crystalline geode. You miss this person, but you have accepted the passing along with the continuing present absence or absent presence. There may even be an enhanced understanding of life – openness to the losses and suffering of others. Spiritual emergency may have opened out into spiritual emergence (Ashley et al., 2008).

This is the way one generally experiences personal crisis or personal disaster, namely losses of many sorts that involve profound transitions – death, divorce, or loss of a job. The ability to 'bounce back' has been one popular interpretation of 'resilience' (e.g., Smith et al., 2008), which has also been advanced as being the ability to 'bounce forward' into a more positive state of mind and higher level of functioning (Manyena et al., 2011). These interpretations have been applied to individuals and collectives, such as ecosystems and human systems. How relevant are such interpretations for communities?

In order to discuss community resilience, it is necessary to define two slippery words: 'community' and 'resilience.'

What is Community?

The term 'community' emerged in the Middle Ages with its origins in 'common,' in the sense of fellowship, public, or joint ownership. Academically, the word might date from nineteenth-century German sociology, since when it has become popular within many diverse disciplines. Its meaning is contested. Bell and Newby (1973) identified 98 different uses of the word and these have expanded (Dominelli, 2006). Additionally, the term may be used to cover up exploitation and conflict (Agrawal and Gibson, 1999; Walmsley, 2006) with Walmsley (2006) particularly highlighting the lack of homogeneity in most communities, despite the term 'community' seeming to imply consistency. Usually in a community, there will be some individuals who are marginalized from access to decision making for reasons including stigma, past history, ethnicity, race, religion, gender, sex, age, ability, health status, immigration status, and sexual preference. There will be individuals with more power, wealth and access to information, financial and material resources – and some with less.

Here, we take 'community' to mean people living in a locality and their extended networks elsewhere in space and time. The latter is important where people believe that their deceased ancestors are an intimate part of their daily lives. The spatial aspect might not be continuous, but the community could involve different groups, which are a large distance apart, such as a diaspora.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28019-7

What Is Resilience?

Alexander (2013) gives a detailed etymology of the term 'resilience,' starting with its Latin meaning of 'bounce' and taking it through more than two millennia until it started to be associated with 'rebounding' rather than just bounce. Into the twentieth century, the term was increasingly used in medicine, engineering, and psychology, followed by natural ecology and then human ecology. In recent decades, economics and development studies among many other fields adopted their own views of the meaning of 'resilience.' For example, Manyena (2006) and Gaillard (2007) provide background and interpretations from a disaster risk reduction (DRR) perspective.

Consequently, 'resilience' and 'resiliency' today have numerous, disparate definitions and interpretations, as does 'community.' Resilience has, therefore, shifted away from simply meaning to 'bounce back' like materials under stress or a biological population in an ecosystem when many individuals are killed by predators or disease (Levine et al., 2012). A common contemporary interpretation based on ecology comes from Turnbull et al. (2013: 9) who define 'resilience' to be:

> … [T]he capacity of an individual, household, population group or system to anticipate, absorb, and recovery from hazards and/or effects of climate change and other shocks and stresses without compromising (and potentially enhancing) long-term prospects.

The basis for this definition has been significantly critiqued (e.g., Lewis and Kelman, 2010). Hewitt (1983) objects to the characterization of disasters as sudden shocks, considering the long-term vulnerability processes, which must exist for a disaster to manifest (see also Lewis, 1999). Certainly, the manifestation of climate change over generations can hardly be accepted as being a shock, which the definition above implies. Meanwhile, Dominelli (2012) suggests that resilience has stochastic properties, which do not always result in a linear movement forward. People could move backward and forward along a continuum that includes lack of extensive resilience, resilience sufficient for survival, or resilience maintaining the previous state (before the disaster); and through to resilience that is transformative and enables people to flourish, thrive, and do better.

Simultaneously, the notion of 'normality' is contested. Wisner (1993) argues that disasters are prefigured in the conditions of daily life. For subgroups within a community who have the least control of the wealth have access to few resources and who suffer discrimination or marginalization, 'normal' life is rife with everyday disasters such as seasonal flooding, shack fires, crime, and abuse by policy makers. Vulnerability to challenges of daily life are ever-present such as getting education and food alongside less usual experiences such as earthquakes and tornadoes (Wisner et al., 2004, 2014). Hewitt (1997: 143) considers vulnerability to be "embedded in the social geography of settlements and land uses, and the space of distribution of influence in communities and political organisation." That is normal, which shows itself to be remarkably resilient. There is no particular reason why, after a disaster, people would desire to 'bounce back' to that state of vulnerability since that normality, that state of vulnerability, caused the disaster in the first place (see also Glantz and Jamieson, 2000).

What Is Community Resilience?

Given the heterogeneity of subgroups within any community – with people stratified in terms of decision making, capacity and vulnerability, by wealth, income and sometimes ethnicity and religion, alongside commonplace differences such as gender, sexual orientation, age, and ability – there are both winners and losers while and after a disaster manifests. Often, humanitarian assistance, recovery, and reconstruction reestablish that status quo because resilience is seen as a return to the predisaster 'normal,' rather than trying to create a different community, which solves the problems that led to the disaster in the first place, frequently espoused by the tagline 'Build Back Better.' By returning to the status quo, vulnerability to disaster remains the same, or can even increase, while capacity and resilience can decrease, instead with those in control gaining resources, capacity, and resilience (Susman et al., 1983).

With risk being an intersection of hazard and vulnerability (Wisner et al., 2004), returning to the predisaster 'normal' can actually increase risk by doing nothing about the hazard while increasing vulnerability; that is, taking a narrow view of resilience can increase risk. Similarly, any lack of risk reduction, risk prevention, or preparedness will simply be reinstated, achieving little with regards to broader views of resilience. Instead, resilience depends on access to various kinds of resources that provide members of subgroups with a community with capacity to cope. The relationship between capacity and access to six kinds of resources is schematized in **Figure 1** (Wisner et al., 2012: 28).

Paton (2007) offers a schema that overviews resilience from the point of view of individuals, communities, and institutions. Under each of these headings, they list a series of characteristics or capacities providing the basis for 'bouncing forward' when a disaster causes disruption and loss. Of note is the recurrence of the word 'resources' in each list, reminding one of the unequal distribution of resources required for the capacities to recovery (and summarized in **Figure 2**) to materialize. The double-headed arrows suggest interaction and complex feedbacks, also noting that institutions upon which communities and individuals normally depend are likely to be disrupted by disaster. Other new institutions can be introduced, including those brought in by humanitarian actors, but their routines and cultures are different (Robinson, 2008).

Community resilience, therefore, involves interactions among individuals, groups, and institutions that usually result in collective action to enhance the capacities for recovering from a disaster. Acts of solidarity with those in need may emerge and transformative structural change could be effected if it is to transcend individual resilience, particularly, among those who are especially vulnerable in a given situation (Dominelli, 2012).

Disasters and Community Resilience

When trying to understand community resilience, it is helpful to examine the range of hazards that may affect a community, stressing component subgroups within that community to differing degrees. Broadly speaking, these fall into four categories, using a mixture of vocabulary, which in itself, can be legitimately challenged: (1) natural (or environment) hazards; (2) technological hazards; (3) violent social crisis such as terrorism and violent crime; and (4) nonviolent social crisis

with examples being economic changes, corruption, and development-induced displacement. In addition to the vocabulary difficulties, this neat typography is troubled by the overlapping insults to minds, bodies, and livelihoods seen in reality – sometimes even perpetuated by the community rather than just happening to the community.

As an example of overlap, natural hazards may manifest themselves, realizing risk, in situations of violent conflict and displacement. On 26 December 2004, an earthquake and tsunami struck Aceh, Indonesia, and then the tsunami spread out across the Indian Ocean with Sri Lanka being the second worst country hit after Indonesia. Both locations at the time were in the grip of a long-running violent conflict. Sexual violence and trafficking in women and children hang over the best-run refugee and postdisaster encampments (Fordham, 2012). Natural hazards often trigger the catastrophic failure of pipelines, refineries, ships, and other technological facilities carrying or storing chemicals, or used for food and water distribution such as harbors and airports, causing additional burdens and losses. Despite humanitarian assistance, a large percentage of small businesses never recover from a disaster, especially when already being impacted by wider scale economic downturns (Sanderson, 2012).

That is, community resilience is not just about dealing with a specific disaster (or 'event' or 'shock') in space and time, but is also about capacities to deal with multiple vulnerabilities and intersecting, multiple hazards leading to multiple risks and crises, any of which might be conjunctive, cascading, or coincidental (simultaneously or not). In a sense, these characterizations are the disaster(s) to which communities seek resilience. Without forgetting these wider contexts, and recognizing that many of the points made in one section apply equally to the other three sections, understandings of community resilience for each of the four categories are now explored further.

Community Resilience and Natural Hazards

Communities may experience severe physical and social (including economic) harm as a result of natural events and processes such as earthquakes, tsunamis, floods, and volcanic eruptions. That is not saying that all such impacts are necessarily damaging or detrimental, since volcanic ash and floodwater, for example, bring nutrients to soil permitting people to live in locations affected by these environmental processes. But the difficulties and disasters should not be denied, even where there are gains as well as losses, and winners as well as losers.

People who lose infrastructure and livelihoods to natural hazards often wish to rebuild in the same place (Oliver-Smith, 1986; Vale and Campanella, 2005) irrespective of the chances of the same hazards recurring. To them, the familiarity of the place and living as they always have done, including owning their land and property if they did before the disaster, is part of their community resilience. While some success stories do exist, so do many failures, with one example being Simpson's (2014) account of the mixed results of humanitarian assistance 10 years after the 2001 earthquake in Gujarat, India.

A misnomer in the disasters field is that reconstruction means recovery and represents resilience. Merely putting up buildings and other infrastructure does not indicate how people, their families, their friends, and the wider social networks are doing. After a flood, are they afraid every time it rains? Were losses compensated for, or do the people need to start over financially? When loved ones are killed, what does 'recovery' mean for those left behind? The answers to such questions are usually different for different social classes, castes, genders, sexes, and other subgroups within a community. Simpson (2014), Boano (2013), and Sanderson et al. (2012), among others, have shown how humanitarian assistance is often skewed in ways that reinforce caste and class differences, wealth and income gaps, and spatial segregation.

As a case study, about one-third of the population of New Orleans, Louisiana never returned after Hurricane Katrina forced a massive evacuation in 2005. These nonreturnees were generally the poorest, many of them African-American, who were evacuated to Houston, Texas, and other cities (Dyson, 2007). Some more affluent residents also chose not to return, but the key word here is 'chose' – they have the power and resources to make their own decision and, as such, could be deemed to be individually resilient. But when large swathes of the population do not have similar choices, then the community can hardly be termed 'resilient' – even if infrastructure is renewed.

Community Resilience and Technological Hazards

The systematic study of the impact of large-scale technological hazards on communities might have begun in Canada with Henry Prince's PhD dissertation on the catastrophic 1917 explosion of a ship in Halifax, Nova Scotia's harbor, which killed approximately 2000 people (Prince, 1920). Canada also provides a contemporary example of a transportation-related technological disaster. In July 2013, a runaway train literally tore the heart out of the small town of Lac Mégantic, Quebec, when cars carrying crude oil derailed and exploded near the town's center, killing 47 people and displacing another 2000 (BBC, 2013). The survivors in Halifax rebuilt their city and lives, while the evacuees from Lac Mégantic are in the process of rebuilding their town, but they will never be able to replace the archives and historic buildings lost. These Canadian cities represent community resilience in terms of living with grief and moving forward from the catastrophe rather than letting the disaster consume them. Community resilience in the sense of returning to the predisaster state could never be achieved, since so much was lost.

Other technological hazards often preclude certain assumptions made about community resilience, such as the generations of Ukrainians and Japanese dealing with the legacy of nuclear power plant disasters. In 1986 at Chernobyl and in 2011 at Fukushima, radiation releases left settlements and the countryside uninhabitable around the plants. Personal stories indicate the challenges of community resilience in the face of permanent upheaval.

Two years after the Fukushima disaster, 150 000 people are still displaced from homes due to radiation. Despite more social services and housing assistance than most people can expect elsewhere in the world, these evacuees are unhappy. In the words of one, "I just want to get our life back to how it was before. We were 20 minutes from both [my wife's and my]

parents. We'd have barbeques on the weekends.… The hardest thing is that we can no longer do the things that seemed so natural before" (Bird, 2013: online). Smith (2013) calculates that the total number of deaths due to the effects of evacuation in Fukushima Prefecture is nearly equal to those killed in the original earthquake and tsunami (Smith, 2013: online):

> Causes of death in the aftermath have included 'fatigue' due to conditions in evacuation centers, exhaustion from relocating, and illness resulting from hospital closures. The survey also said a number of suicides had been attributed to the ordeal. Francis Markus, East Asia spokesperson for the International Federation of Red Cross and Red Crescent Societies (IFRC), said the conditions faced by those displaced is made worse by them not knowing when they can return.

One of the greatest challenges to community resilience, as seen by the effects on emotional well-being and other mental health aspects, is long-term or permanent displacement from one's home (Long, 2011).

Community Resilience and Violent Social Crisis

Communities experience many forms of disasters linked to violence, such as terrorist attacks, gun massacres, and assassinations, all of which illustrate aspects of community resilience. In these cases, as in all others, there is differential distribution of resources (**Figure 1**) that fuel the capacities required for resilience (listed in **Figure 2**). This holds within subgroups of communities as well as applying among whole populations and societies. Communities affected by violence, e.g., in Argentina, the USA, and Democratic Republic of Congo (DRC) do not have access to the same resources. Some other reasons include struggles over resources, but also, religious and nationalistic claims – how people see themselves in the world.

Activism in emergent groups working to prevent a recurrence of violence and to heal the emotional wounds may provide new, supplementary, spatially diffuse communities of experience and solidarity. These include those like the 'Mothers of the Disappeared' in Argentina (Hernandez, 2012) and 911 Families Association (http://911families.org/) in the USA, and may provide a way that gives the personal and collective loss meaning. Not all groups have such options, such as those who experienced rape used as a war weapon in DRC over past years. With some minor, externally funded exceptions, the women and girls affected have few options to create solidarity among themselves and to provide collective remembrance, because they have little or no political voice and resources (Women's Institute for Gender Justice, 2013).

Other populations have managed to set up collective processes, ostensibly for everyone, to try to build community resilience after a violent period. The process known as 'truth and reconciliation,' often associated with South Africa's post-apartheid coming to terms of that period but also replicated across many other postconflict situations, is controversial. Some assert that transparency and confession of violent acts by the perpetrators are part of the necessary honesty, grieving, and healing to ensure that the society does not return to 'normal,' but instead accepts what happened and moves on to do better. Others suggest that such a process leaves those who suffered violence unsatisfied when there is no punishment. It is easy to speak philosophically of restorative vs retributive justice when one has not been victimized or known someone who was tortured or killed (Kruks, 2012). In reality, it can be much harder to feel resilient or to support community resilience when those who caused suffering suffer no consequences.

Community Resilience and Nonviolent Social Crisis

Community resilience is being used as a tagline to deal with expectations of long-term, nonviolent crises, such as reduced availability of natural resources and creeping environmental changes including climate change. 'Localization' movements have emerged, seeking to make food, water, energy, livelihoods, and money much more local and hence less dependent on external factors or national support. Localization is seen as building community resilience by being able to deal with crises in the absence of external support.

An example is concerns about limited fossil fuel supplies, because the cost becomes prohibitive, supply is disrupted, or diminishing resources – all of which are linked. Consequences envisioned of limited fossil fuel supplies include food availability being reduced because vehicles have limited petrol to transport supplies to supermarkets; blackouts during hot and cold temperature extremes because electricity generating plants depending on fossil fuels must shut down; and emergency services being unable to respond promptly due to petrol restrictions. Making food, water, energy, and manufacturing more locally based reduces dependence on fossil fuels.

Localization also helps to build community resilience against other major disruptions, such as economic instability, a rapid decrease of water resources, and the sudden decentralizing of large sovereign states – with a prominent example being the sudden dissolution of the USSR in 1991. Some of the USSR's allies, such as Cuba, lost a major supplier and rapidly had to adjust to the lack of food and fuel being imported.

Building community resilience to nonviolent social crisis is much more than considering what happens externally to a community. It is also about the community itself. The construction and perpetuation of poverty can be due to deliberate exploitation of people and the construction of a social order favoring those with power, a process termed 'quiet violence' (Hartmann and Boyce, 1984), which effectively precludes a community resilient to anything. Vulnerability and lack of capacity to reduce it, and to build resilience, are aggravated by poverty, preventing any opportunity to 'bounce forward' after other hazards impact. Due to the persistent, ongoing crisis of poverty, it is hard enough just trying to 'bounce back' to the original state of poverty, so community resilience becomes a dream rather than a goal, blocked by the same powers, which create and perpetuate poverty in the first place.

Community-Based DRR

In the face of all these diverse challenges, with the inherent barriers and opportunities for community resilience,

what practical measures should communities implement? Numerous approaches have been developed and tested, inviting and supporting groups of people living in the same localities – communities or subgroups therein – to assess the specific hazards or crises they face; to identify and analyze the people, livelihoods, places, and assets in harms way (effectively vulnerability); and to appraise their own resources and capacities to reduce losses or even to prevent the hazard or crisis, thereby further indicating what external support they might need.

These approaches are embedded within the communities, but can be facilitated by external people so that no one in the community is left out and to ensure a balanced approach. This suite of methods has become known as Community-based Disaster Risk Reduction (CBDRR), which here, provides an operational process for supporting community resilience (e.g., **Box 1**). The importance of CBDRR is now recognized by most organizations working in DRR and is also promoted through the London-based Global Network of Civil Society Organisations for Disaster Reduction (GNDR, 2011).

As shown by **Box 1**, one of the keys for successful CBDRR for building community resilience is to ensure full and fair participation by all those in the community, but without necessarily handing over full control of the process to community leaders. As with everyone, community leaders have their biases and prejudices, which can inhibit resilience building. In fact, one interesting part of many participatory processes for CBDRR, including P3DM, is that neither the external participants nor community members are able to achieve the best results for community resilience on their own. Instead, the parties learn from each other, exchanging knowledge and wisdom, meaning that those external to community take plenty back with them to build resilience in their own community – if they choose to do so, preferably with external supporters for their own CBDRR.

Box 1 Participatory 3-Dimensional Mapping for enhancing community resilience to disasters

Participatory 3-Dimensional Mapping (P3DM) consists of building stand-alone large-scale relief maps made of locally available and cheap materials (e.g., carton, paper, cork) on which people place thematic layers of geographic information. P3DM enables the mapping of landforms and topographic landmarks, land cover and use, and anthropogenic features, which can be depicted by push-pins (points), yarn (lines), and paint (polygons). Participants plot land use and other geographical features and differentiate them according to their vulnerability. Pins of different shapes, sizes and colors can differentiate building materials and can locate the most vulnerable people in the community.

Community members can also delineate hazard-prone areas and locate local resources for dealing with hazards. It is then easy and quick to evaluate disaster risk based on hazards, threatened assets, vulnerabilities, and capacities. P3DM enables the planning of DRR measures to enhance community resilience based on multistakeholder group discussions, helping to find consensus among participants.

As such, P3DM fosters the participation and collaboration of a large range of stakeholders, including scientists, government officials, NGOs, and local communities, permitting the integration of bottom-up and top-down DRR measures. P3DM provides a tangible tool in which the most marginalized people, who may have a poor understanding of scientific concepts, can discuss DRR with scientists, who may have a poor understanding of the local context. All stakeholders can contribute their knowledge on the same tool and in the same forum. P3DM is credible to locals, who build the map and plot most of the information, and to scientists alongside government representatives who can easily overlap their own data and plans on scaled and geo-referenced maps. In the process, NGOs often serve as facilitators and moderators.

Despite all its advantages, P3DM is not a stand-alone tool and needs to be combined with other participatory tools. The reason is to capture dimensions of vulnerabilities and capacities, which are difficult to plot on a map, e.g., interpersonal relationships and temporal patterns. In addition, as for all participatory tools, the contribution and sustainability of a P3DM project depend upon the process of participation and the respect of local needs and aspirations. Having a pretty map is not an objective per se. Instead, it needs to be used to foster a dialogue among those involved for DRR, to facilitate disaster risk assessment, and to contribute to enhancing community resilience.

Conclusions: Resilience and Transformation

In the end, one must consider accumulating doubts about the uses of the word 'resilience' in the context of major challenges to the physical and mental well-being, assets and livelihoods of subgroups within communities – placing those doubts beside doubts about the word 'community.' Such doubts apply to all the categories described above. Too often, the use of the term 'resilience' is reductionist and technocratic, assuming that ecological concepts can be mapped directly onto society. Mechanistic approaches can masquerade as being all-encompassing, such as 'socioecological systems' dominating much community resilience work, when in reality, many (not all) such analyses emphasize paradigms from ecology, while obscuring the deeper politics of risk, power, equality, and access to resources.

Because such standard approaches are not achieving community resilience, as evidenced by increasing and expanding disaster losses, especially affecting those in society least able to cope with the losses (GNDR, 2011), many are now calling for community resilience to be achieved by transformation and transformative processes. Academic work has a long pedigree of analyzing societal transformation (e.g., Polanyi, 1944; and all the ensuing critiques, e.g., Lie, 1991). Major transformations have certainly been achieved in the past – such as banning slavery, outlawing smoking in indoor public places, and permitting women to vote – but what does it mean for community resilience to disasters?

The answer is that the contemporary discourse might be somewhat naïve in expecting communities to build resilience through transformation. As we have seen, the fundamental resilience challenges in communities emerge at the basic level: individuals and families dealing with reality day-to-day, on top which a rarer hazard might manifest, all of which can lead to disasters. Similarly, we have seen how the fundamental solutions to building wide concepts of resilience to disasters, including the day-to-day disasters,

come from the community at the basic level: individuals and families making better use of what they have already, including knowledge and assets.

Community resilience to disasters does not mean keeping the status quo nor does it mean sudden, overwhelming change. Instead, it means continuing to improve over the long term and seeking changes at all scales so that people have increased access to options and resources to help themselves do better in maintaining rewarding livelihoods and in living. That builds toward the long term, sustained process of resilience that communities need to reduce the risk of disaster.

Abstract

Sociologists have focused in various ways on the structures, institutions, social relations, and economic changes affecting communities. Insights have been provided by community studies and through the broadening perspectives developed by urban sociology. With developments in social and cultural theory, researchers have increasingly emphasized the ordering of social life by meanings, beliefs, identities, and cultures. All this has produced multiple interpretations of the word *community* with contending approaches and interpretations.

Community Sociology

Sociologists have focused in various ways on the structures, institutions, social relations, and economic changes affecting communities. With developments in social and cultural theory, researchers have increasingly emphasized meanings, beliefs, identities, and cultures in ordering social life. All this has produced multiple interpretations of community, with contending approaches and interpretations.

The Classical Sociologists

The classical sociologists addressed changes taking place in modern society and how those changes affected social and communal relationships. The classical sociologists expressed a sense of something lost relating to community.

Auguste Comte, in *The Positive Polity* (1851–54), gave a utopian response to modern society. For Comte, the conditions existed for the creation of an ordered science- and technology-based society. He envisaged the restoration of morality and community with a new business class leading the march to social progress. Comte's moral community was hierarchical and corporatist, with positivist society subsuming the individual and the family in inculcating moral authority.

Frederic Le Play, in his 1855 six-volume work *The Workers of Europe*, employed social survey techniques to analyze differing patterns of kinship and community, with reference to types of family organization. With family life challenged by economic change, the prospect for communities was a future of insecurity and social disorientation. Le Play saw the family as being crucially important in relating individuals to the wider community, thereby providing a moral foundation for and a stabilizing influence on social intercourse.

In 1887, Ferdinand Tönnies, in *Gemeinschaft und Gesellschaft* (see Harris, 2001; Loomis, 2002) produced an ambitious and complex study of social change and individual and group relationships (Harris, 2001: xv). The essential union in Gemeinschaft was the family with its sense of blood, kinship, friendship, and place. Associations of Gemeinschaft were guilds, churches, fellowships, and so on, where people shared common beliefs and ways of working. In all these associations, ideas of family and hierarchy remained strong. The combination of Gemeinschaft unions and associations thus reinforced a strong notion of community and mutual cooperation. With the mechanical society of Gesellschaft, people associated on the basis of ends, means, and rationality, which were foundations of the modern commercial enterprise with its emphasis on regulation. Association was no longer based on kinship or friendship but on rationality and calculation, indicating a move away from community. In Gemeinschaft, "individuals developed their identities within the wider, co-existing, whole," whereas in modern civil and commercial society "individual identity was ontologically prior to that of the wider group, attachment to which was merely secondary and instrumental" (Harris, 2001: xviii). In Gesellschaft, individuality and production for profit had priority (see Nisbet, 1966: 75–75).

There was a similarity between Tönnies and Max Weber concerning the 'falling away' from 'patriarchalism and brotherhood' (see Nisbet, 1966: 39). For Tönnies, Gesellschaft provided the explanatory process for the decline of community whereas Weber confirmed the importance of the communal ethic and regarded the falling away as the result of rationalization. Despite the influence of Tönnies on Weber, Nisbet (1966) argues that Weber presented a more subtle and sophisticated treatment of social action and community, focusing on types of solidarity in social relationships and group interests that engendered collective identity. Weber pointed to distinctions between the ideal types of communal and associative solidarities. Communal relationships involved a subjective sense of togetherness as found, for example, in families, neighborhoods, and religious groups, and they involved people in voluntary association based on common interests or beliefs. Associative relationships arose from rational calculation of interests as, for example, in the economic market. The closure of either type of relationship protected them, whereas open communal and associative relationships were subject to the erosion of coherence and allegiance.

In 1893, in *The Division of Labor in Society*, Emile Durkheim referred to mechanical and organic social solidarity. The basis of mechanical solidarity was moral and social cohesion expressed through small communities where the individual was subject to the collective conscience. The basis of organic solidarity was the division of labor in which individuals became disengaged from traditional class, kinship, and collective conscience. Durkheim later modified his position by

recognizing social facts that reinforced tradition and constraint. Durkheim "transmuted the attributes of mechanical solidarity into the eternal characteristics of social facts in general" (Nisbet, 1966: 86). An underlying message was that excessive individualism would lead to 'anomie' (without law) and the consequent breakdown of moral community.

Georg Simmel (2002[1903]) also problematized the situation of the individual in modern society. He regarded the individual in the context of the growing modern metropolis where the division of labor and economic market exchange produced alienation and social isolation. This made the individual vulnerable to the danger of subordination to the 'mass.' Simmel, therefore, underlined the value of voluntary associations and the danger to them posed by impersonal state institutions.

Early Community Studies

New thinking in the United States around the turn of the twentieth century signaled a growing concern of sociologists with issues having to do with the specific experiences of real communities. William Du Bois documented the plight of African-Americans in his 1889 work *The Philadelphia Negro*, which represented growing interest in the problems of urban African-Americans (Green and Driver, 1978).

After the First World War, sociologists in the United States studied community experiences against a backdrop of social and economic uncertainty. Various sociological and social anthropological methods and approaches were employed, and the genre of community studies developed as a distinctive approach in which researchers selected a single community as a cultural sample, commonly with the researchers living within the community while conducting their investigations and producing noncumulative findings.

The classic social anthropological community study by Lynd and Lynd (1929), *Middletown: A Study in Modern American Culture*, viewed life in a small American city (actually Muncie, Indiana). This was a predominantly white community having a 'middle of the road quality.' Adopting a functional cultural approach, they viewed employment, homemaking, leisure activities, religious practices, 'training the young,' and community involvement over a 35-year period, and in a follow-up study (Lynd and Lynd, 1937), they showed how Middletown had adapted to changing economic fortunes during and after the Great Depression. The Lynds found Middletown divided, with a dominant business class and a working class that had become less unionized and less politically active.

Also within the genre of community studies was the work of anthropologist Lloyd Warner and his colleagues, who produced their Yankee City studies (actually Newburyport, New England) between 1941 and 1959. They adopted a variety of research techniques, including observation, interviews, and documentary analysis, resulting in a view of Yankee City in terms of social-class divisions. Influenced by Warner, social anthropologists Allison Davis et al. (2009[1941]) viewed class and caste distinctions in their study of American communities in the Deep South (in the 'old city,' or Natchez, MI), and psychologist John Dollard (1937) in *Class and Caste in a Southern Town*, studied class and caste divisions, arguing that caste differences affected community social structures and impacted both black and white ethnic groups.

Another notable community study of this era was William Whyte's (1993[1943]) *Street Corner Society*, based on the results of participant research within the Italian North End slum district of Boston. Whyte provided a vivid picture of life in the ethnic enclave. The study presented a snapshot of a community with a strong sense of cohesion and internal organization.

Colin Bell and Howard Newby (1971) pointed to serious flaws in the community studies 'method.' They argued that ethnographic community studies often produced overly sympathetic accounts of community life, particularly when the researchers became closely involved with the neighborhoods studied, and that the noncumulative nature of the studies restricted an appreciation of wider societal implications. Nevertheless, the community studies carried out between the 1920s and 1940s provided some graphic insights into the life experiences of people in small-town and rural America and are still of interest socially and historically.

The Chicago School

Apart from such community studies, sociological interest in the 1920s and 1930s in the United States focused increasingly on the experiences of groups in cities, and interest in urbanism provided some of the most innovative and challenging sociological research of the time.

Chicago epitomized the twentieth-century American big city with its diverse cultures, impressive skyscraper buildings, and rapid urban expansion. Sociologists at the University of Chicago concentrated their research on this experience, in which migrants from Europe engaged in establishing new communities in teaming modern metropolises and where people sought betterment rather than revolution.

Although it is possible to bracket the Chicago School under the heading of community studies (Bell and Newby, 1971: 55), it is appropriate today to regard the Chicago School as having made a distinctive contribution that provided a more theoretically sophisticated body of work than community studies and established an 'urban sociology.'

Robert Park inspired the Chicago School, and Peter Saunders (1986: 53) discerned in Park's urban ecology the influences of Auguste Comte, Georg Simmel, Emile Durkheim, Charles Darwin, and Herbert Spencer. Saunders maintained that Durkheim influenced Park's ontological assumptions regarding human nature, the relationship between the individual and society, and the conditions for social order, wherease the Darwinian influence showed in Park's regard for cities in terms of urban ecology, where humans constantly adapted to and negotiated with their environments. In this, Park referred to community as 'an object of analysis,' an 'ecological process,' and a 'biotic level of social life' (Saunders, 1986: 53, 55). Here, there was ongoing competition for survival and a tension between the flights of human nature and the need for moral constraint.

Robert Park et al. (1925) portrayed urban neighborhood organization with respect to the idea that cooperation and

competition were foundations of intergroup relationships. Underlying tensions undermined social control, but communities achieved order through social specialization and interdependence. Park (1952) linked the inherent competitiveness of urban life to the struggle to control scarce resources, and other Chicago School sociologists went on to emphasize human struggle within cities and the consequent adaptation of social organization to change.

The urban ecologists interpreted the relationship between urban and rural in the same terms. Louis Wirth (1938: 7) argued that cities were expanding outward into rural areas through a process of urbanization that blurred the distinction between urban and rural. Increasingly, rural life bore "the imprint of urbanism in the measure that through contact and communication it comes under the influence of cities." Cities were relatively large, densely populated, and socially heterogeneous. Variations in size, density, and heterogeneity produced varied patterns of human association. Density was a function of differentiation, with groups tending to congregate in specific locations. For Wirth, competitiveness among urban dwellers and the superficiality of urban social relations resulted in a social psychology of urban life in which class and ethnic affinities became less important. For Wirth, cities were impersonal, with divisions between people producing different ways of life that made consensus and stable community life difficult to achieve. As Robert Sampson (2012: 427f) notes, Wirth linked community 'diversity with decline' by focusing on social disorganization. This contrasted with Whyte's socially organized slum and with the findings of several later studies that pointed to the sustained cohesion of rural and urban communities.

The postwar period presented new challenges to which the Chicago School urban ecology was incapable of responding, and Sampson (2012) has pointed to major methodological challenges in ecological research in the 1950s. Ray Phal (1968) argued that Wirth's description of inner cities did not hold up in the postwar context. The characteristics of modern inner-city communities were different from those described by Chicago School sociologists, and Herbert Gans (1968) criticized Wirth for having inappropriately generalized lessons from the inner city to wider urban areas and suburban communities. Wirth's size, density, and heterogeneity criteria did not explain broader urban change, and causal relationships among the criteria were not established.

Although the Chicago sociologists inspired in various ways those who later emphasized the social construction of 'the phenomena of daily life' (see Sarbin and Kitsuse, 1994: 3 for a wider discussion of the influence of Chicago in this respect), the ecological approach nevertheless lost its appeal. The Chicago influence faded as sociologists turned away from ecological explanations of spatial variation that failed to provide an adequate basis for theorization about social relationships and perceptions of community.

Tradition, Power, and Later Community Studies

American conservative sociologist Robert Nisbet (1953) proposed a functionalist view of community. He advocated a reconsideration of the traditions and collective values of communities. For Nisbet, the concept of community "encompasses all forms of relationship which are characterized by a high degree of personal intimacy, emotional depth, moral commitment, social cohesion, and continuity in time" (Nisbet, 1966: 47). Community engendered "a fusion of feeling and thought, of tradition and commitment, of membership and volition" given symbolic expression by 'locality, religion, nation, race, occupation, or crusade.' Nisbet argued that historically people were on a 'quest for community' that sought to rediscover the foundations of moral order and cohesion. However, in modern society, it was difficult to realize true community, so people turned to substitutes to reignite a sense of collective togetherness. Totalitarian political movements or the state often fulfilled the role of providing comradeship, national identity, and welfare provision.

Despite its nostalgic appeal, the quest for traditional community neglected the crucial issue of local power. In the 1950s and 1960s in the United States, controversy thus arose over the nature and distribution of community power and the implications for democracy. Sociologist Floyd Hunter (1980 [1969]), in *The Community Power Structure: A Study of Decision Makers*, pointed to the influence of powerful elite decision makers in Atlanta (which he called Regional City). Hunter referred to racial segregation and social privilege in the city, and sociologist C. Wright Mills (1956) identified a Power Elite presiding over politics and society in the United States. By contrast, political scientist Robert Dahl (1961) provided a classic pluralist interpretation of local politics in a study of New Haven, CT. There he claimed, polyarchy represented the rule of the many where power was unequally distributed, but where groups could influence crucial local political decisions.

Internationally, some sociologists and others continued to work within the community-studies genre, but community studies failed to come to terms adequately with some of the broader influences bringing about community change. The genre still drew on its functionalist foundations, and Graham Day (2006) critically reviewed postwar community studies with reference to, for example, Margaret Stacy's (1960) study of English small-town Banbury. Day (2006) highlighted the limitations imposed by "treating communities as though they were free-standing entities" (Day, 2006: 152). Given controversies about community power, urban deprivation, and ethnic minorities, researchers therefore came increasingly to view communities in terms of wider structures and processes by placing greater emphasis on social class, ethnicity, gender, and social conflict.

Class, Ethnicity, and Gender

British sociologists Michael Young and Peter Willmot (2007 [1957]), in *Family and Kinship in East London*, exemplified the broadening of the research horizon. The East End had traditionally served as a point of entry for immigrant groups, such the Huguenots and Jews. However, Young and Willmot warned of the disruptive effects of urban renewal on traditional working-class communities. They pointed to the bonds and kinship affiliations that made the East End work,

but public planning policies were disrupting communities by displacing people to new towns beyond London and through the construction of mass housing projects that took no account of the informal networks so important to community life.

In the United States, urban communities were also undergoing change. Herbert Gans (1982[1962]: ix), in his sociological study of Boston's West End, sought to 'generalize beyond the community study' by viewing social class and community change. Gans lived in the West End between 1957 and 1958, shortly before the area's comprehensive redevelopment. For Gans, the West End was understandable in terms of class rather than white ethnicity. Before clearance, the West End was a cohesive white working-class Italian community in the heart of Boston that was "an ethnic goldfish bowl in which privacy and nonconformity were rare" (Gans, 1982[1962]: xi). However, like Young and Willmot, Gans witnessed the disruption of the community through urban renewal – a process that he criticized following extensive interviews with West End residents affected by relocation to other areas.

The West End study added to concern about the condition of American cities and problems of urban communities. Community activists in the United States sought to empower communities by operating within the political system, and policymakers and politicians prioritized urban policies to address post-industrial urban decline by engaging local communities through participatory initiatives. In the United States in the 1960s, studies viewed the 'ghetto' and experiences of racism, sexism, social exclusion, and poverty set against the backdrop of urban and industrial decline (for example Jacobs, 1966; Hannerz, 1969). These issues became more pressing in the wake of serious urban riots in the United States in the 1960s, with community-based activist groups such as the Black Panthers advocating black power and direct action. Feminist groups also become more influential as evidenced by American sociologist Nancy Naples (2008) who have viewed feminist activism from the 1960s onward and the links among feminism, race, and class.

Sociologists John Rex and Robert Moore (1967) addressed themes of exclusion confronting ethnic minorities in England. They studied ethnic minority access to housing in the Sparkbrook district in the English city of Birmingham. Adopting an approach influenced by Weber and Burgess's work on Chicago, they showed how the interaction of social and spatial conditions influenced peoples' goals. Sparkbrook had experienced economic decline while attracting black and Asian immigrants from overseas. Some managed to acquire housing in better areas while others could obtain access only to poorer housing in rundown districts. Rex and Moore viewed the differentiation and spatial segregation of communities. The middle class tended to move to suburban areas while inner city areas concentrated the new migrants, where they experienced racial discrimination and bureaucratic city council housing policies.

Pahl (1975), adopting a neo-Weberian approach, regarded urban state bureaucracy in Britain as a mechanism restricting the access of local people to urban services, with planners and officials shaping cities with limited regard of the interests of local people. Planned urban housing projects lacked social and leisure facilities and failed to provide solutions to the problems of cities that were experiencing urban decline.

New Attitudes, Neo-Liberalism, and the Market

Changes in social attitudes and the achievement of black civil rights in the United States during the 1960s and 1970s helped minorities and other excluded groups to gain access to the political system and articulate community-level demands more effectively. However, disillusion among policy makers and the public with state interventionism brought a paradigm shift favoring neoliberal market reforms, private enterprise, and consumerism. The election of Conservative Prime Minister Margaret Thatcher in the United Kingdom and Republican President Ronald Reagan in the United States reflected the mood of the times.

Sociologist Terry Nichols Clark and political scientist Vincent Hoffmann-Martinot (1998) pointed to the emergence of a post-1960s New Political Culture (NPC) that accompanied major changes in social attitudes and aspirations that underlay the growth of market individualism and the lessening of collectivism. The NPC increased the salience of issues such as the environment, citizen democracy, gay rights, abortion, and lifestyle in urban and community politics. Politics placed less emphasis on class and workplace and greater stress on single issues championed by diverse groups within a complex and changing sociopolitical environment. The NPC challenged traditional political parties and old state hierarchies and undermined the assumptions of the postwar welfare state. People were more skeptical about large public bureaucracies and likely to support human-focused policies, smaller and more localized government units, and more responsive forms of local democracy. The NPC emerged "more fully and forcefully in cities and countries with more highly educated citizens, higher incomes, and high-tech service occupations" (Clark and Hoffmann-Martinot, 1998: 3). This marked a change in the ways local communities articulated social and political demands. Local groups were more likely to organize across social class lines as they adopted new modes of social and political action. Information technology opened new horizons by providing opportunities for more effective networking and communication.

Despite the appeal of the market, Mark Gottdiener (1994) identified a radicalizing 'new urban sociology' that emerged during the 1970s, with its interest in social and class conflict in cities and communities. This included work by Marxists such as Manuel Castells and others who sought to develop critiques of neoliberalism and modern market capitalism through studies that broadened the critical research agenda, thereby regarding community within the wider contexts of social change (see below). For example, Castells (1977, 1996) regarded the political economy of urban and community change with regard to modes of capitalist production and the role of communities in the economic processes of accumulation. The neoliberal project, for Marxists and other radical researchers, marked a period of capitalism that consolidated social and economic inequalities and led to the emergence of new forms of local activism and community resistance.

Regime theorists focused on new configurations of economic and political power affecting cities and communities by viewing the impacts of the neoliberal market and the interests of different groups contending for scarce resources. Groups could influence the policy agenda in new ways in cities where conditions were conducive to cooperation. Urban regimes brought together public, private, and political interests that otherwise might conflict so as to boost city economies and market competitiveness. In his urban regime study of Atlanta, political scientist Clarence Stone (1989) assessed changes in the city since Floyd Hunter's (1980[1969]) classic study. Stone showed how a biracial coalition had become part of the city's urban regime. Coalition building helped black politicians access the political system from which they had for so long been excluded and in a city where communities had been racially segregated. Stone's Atlanta story was indicative of change in other cities where African-Americans and other minority groups began to exert political and cultural influence.

The persistence of social exclusion and inequalities demonstrated that market-oriented policies did not automatically guarantee social benefits. Charles Murray (1990) provided a popularized conservative view of the consequences in deprived urban communities of a welfare-dependent underclass the members of which lacked ambition and sense of being responsible for their own futures. Like Murray, sociologist and communitarian Amitai Etzioni (1995, 1996) called for greater moral responsibility and advocated a return to moral values and a greater sense of community and enterprise, while others pointed to social networks as being important in patterning relationships among members of local communities. The idea that cooperation and mutuality produced social benefits featured widely in discussions about viable communities. Public-policy specialist Robert Putnam (2000), in a popular study, found that 'social capital' had declined in communities in the United States. Communities once produced high levels of social capital, but they now had low levels of membership in local organizations and clubs and lower levels of local social support. Earlier, sociologists Harrison White (1963) and Claude Fischer (1982) had developed social-interaction models showing how networking influenced local organization, and sociologist John Scott (2004[1991]) showed how social networks of people influenced local relationships among actors in communities.

The Cultural Turn and Socially Constructed Communities

Sociologists, social theorists, cultural theorists, and those involved in the more broadly defined multidisciplinary field of cultural studies variously resituated socially constructed communities within wider theoretical projects related to social and cultural change. Social theorists came to view communities in the context of broader processes of change by challenging modernist structuralist assumptions in urban sociology. The 'cultural turn' brought about a radical change in the way in which many social researchers understood community in terms of postmodernity.

Geographer Edward Soja (2000, 2010) argued that the cultural turn created a new agenda for researchers – a move away from categorizations of community and social class toward concern with the "more cross-cutting and inclusive foundations of solidarity, collective consciousness, and coalition building" (Soja, 2000: 279). For Soja, this represented a shift away from concern with equality (race, gender, and class inequalities as evidenced in post-1960s urban sociology) toward new conceptions of justice relevant to groups forming new kinds of local-level coalitions.

Sociologists Scott Lash and John Urry (1987) integrated post-Fordism in their postmodernist work *The End of Organized Capitalism*. Henry Ford's modernist mass-production factories had given way to high-technology production located globally, including in countries such as China, South Korea, and India. The post-Fordist regime of accumulation replaced centralized mass production and mass consumption and ushered decentralized flexible specialization, customization, and the growth of service- and information-based activities. Lash (1990: 33) maintained, however, that postmodernism could actually produce 'a strong sense of locality' that, he argued, resembled the Greenwich Village-type of community spirit and diversity depicted by Jane Jacobs (1961). New social movements frequently had community-focused aspirations, along with "a heightened sense of the mix of ethnicity and diverse cultural groupings" that "foregrounds also a sort of metaphysics of 'the street' " (Lash, 1990: 33).

Lash argued that postmodernism could "foster radical-democratic and decentralized worker resistance" offering a vision favoring "community, street, and 'the labyrinth'" (Lash, 1990: 37). However, Lash (1990: 37) also referred to the 'fragmentation of opposition into decentralized social movements' and the resurgence of competitive market individualism at the expense of labor unions and traditional social organizations. In this context, governments attempted to foster market-oriented governance while 'oppositional postmodernism' expressed the desire for community. There was, then, a process of organization and disorganization whereby formally organized interests (such as trade unions and working-class organizations) were 'less coherently structured' and confronted an ideological crisis. This led to "the literal social disorganization of urban blight and violent rebellion by minority and marginal groups whether in Detroit, Liverpool's Toxteth, or Berlin's Kreuzberg" (Lash, 1990: 38).

Others, who we might regard as working within cultural studies (as distinct from specifically postmodernist cultural theory), provided insights into meanings and identities in society and local communities. For example, British social anthropologist Anthony Cohen (1985) portrayed community as a symbolic construct. For Cohen, although the physical geographical bases of community had diminished in importance, there had been a renewed assertion by communities of symbolic boundaries that demarcated one community from another. These boundaries came in many forms, such as rituals and customs that reinforced community identity, membership, and allegiance. The community could "make virtually anything grist to the symbolic mill of cultural distance, whether it be the effects

upon it of some centrally formulated government policy, or a matter of dialect, dress, drinking or dying." This reflected "the contrivance of distinctive meanings within the community's social discourse" (Cohen, 1985: 117). Cohen saw this as indicating the strength of communities because people could achieve collective identify based on strong ethnic, religious, and social symbolism. Benedict Anderson (1991) similarly detected strong identities in communities and culturally expressed through nations as imagined communities.

The Spatial Turn

Theorists concerned with social change variously came to recognize the need to address socially constructed spatiality in contextualizing urban and community change. Indeed, researchers from various disciplines contributed to a 'spatial turn' (Warf and Arias, 2009) that heightened the significance of socially constructed space in accounts of urban and community life and the emergence of new social movements.

Soja (2009: 24) advocated integrating spatial analysis with cultural theory. Soja refers to the 'defensive disciplinary response' to the spatial turn, notably in geography, but also in other disciplines that "often involved a vigorous rejection of the postmodernist critiques that were so closely associated with the spatial turn." Nevertheless, theorists across various disciplines witnessed a significant 'reconfigurative diffusion of spatial thinking' in the social sciences and humanities (Soja, 2009: 25).

Castells (1977), in *The Urban Question*, identified cityspace and activist 'communities of resistance.' For Castells, people in communities could bring about change if they organized themselves effectively. The conflicts among the state, capital, and new social mobilizations involved spatial contestations over cityspace. Capital and the state attempted to create cityspace in their own image, with state authorities and corporations parceling land and redefining the boundaries of neighborhoods. This constant process of reorganization frequently encountered locally organized opposition.

Soja's (2000) *Postmetropolis* depicted a fragmented postmodern urban-regional landscape in Los Angeles that produced 'unjust geographies' (Soja, 2011). Soja referred to the 'jumbled spatiality of the globalized post-Fordist exopolis' characterized by the restructured and fragmented city with its complex 'social mosaic' (Soja, 2000: 265). For Soja, cities juxtaposed meanings and experiences and generated multiple ambiguities. The post-Fordist exopolis was 'sociality' arranged "in complex patterns that are only beginning to be recognized, understood, and effectively studied" (Soja, 2000: 265). Although 'significant communities persist and cannot be ignored,' the new urban social order was no longer defined 'effectively by such conventional and familiar models of social stratification' as the class divided city; the 'neatly layered' hierarchical city or the racially divided city (Soja, 2000: 265). While such 'older polarities' still existed, the most developed cities in terms of their postmodern characteristics were fractal and productive of new social geometries.

Postmodernists frequently referred to the influence of Michel Foucault (1970[1966]), who conceived of heterotopias that in different ways immersed people in contexts that combined different spatial elements, changed over time, supported particular ways of behaving, and gave rise to different constructions of meaning. Heterotopias, such as gated communities, atria-enclosed shopping malls, private lifestyle and leisure spaces, and commercial enclaves generated new identities and ways of thinking about the self in different cultural contexts. Researchers alluded to the privatization of urban space and the social implications of segregated communities and inequalities. For example, Anna Minton (2009), in *Ground Control*, explored the privatization of urban space, social control, and surveillance. Mike Davis (1992) referred to the consequences of segregation and exclusion in communities in Los Angeles.

Marxist geographer David Harvey portrayed people and communities involved in defensive struggles against the destabilizing economic forces of crisis-ridden capitalism. Harvey (2011) has argued that capitalism spatially creates room for accumulation. Global capital is more assertive in creating new spaces of accumulation and consequently creates new sites of struggle and the potential of 'rebel cities' where activists mobilize around a variety of locally salient issues (Harvey, 2012).

Globalization

Sociologists, cultural theorists, and others commonly contextualized change with reference to globalization and the geographic and social mobility of people. The rise of mega-cities with populations of 20 million or more raised concerns about social cohesion and the implications of global shifts of migration, the creation of informal settlements, and poverty and social exclusion.

Castells, acknowledging Howard Rheingold (1993), argued that new information technologies integrated the world through global networks and a 'vast array of virtual communities' (Castells, 1996: 22) that networked groups and individuals in the 'network society.' The Internet and 'electronics grass-roots culture' (Castells, 1996: 354) enabled individuals to interact globally, but also privately. For Castells, the new globalized and customized mass media permeated all levels of society, directly affecting the local community and the individual while Roland Robertson (1995) argued that globalization reconstructed and produced new cultural conceptions of home, community, and locality. Glocalization combined a global and local perspective where local individuals, communities, and companies were oriented to the global.

Sociologist Saskia Sassen (2001) studied the global city, in which dramatic changes affected local communities. Migration and concentrations of global capital led to global cities' becoming vibrant centers of culture and economic activity. In developing nations, global cities acted as network hubs bringing together financial institutions, corporations, and people in a globalizing context. These attracted people from rural to urban areas. However, some cities missed out, and some poorer mega-cities and urban centers failed to achieve global status, thereby marginalizing local communities within the globalizing economy.

Michael Young, with colleagues Geoff Dench and Kate Gavron (Dench et al., 2006), in a follow-up to the original Young and Willmott (2007,[1957]) research already mentioned, regarded a globalized London by viewing the consequences of change for the 'historic working class' and the growing Bangladeshi communities in London's East End. The East End communities are seen in terms of ethnic identity and cross-cutting class cleavages with "cycles of conflict, competition and eventual accommodation between incoming groups and local residents" (Dench et al., 2006: 15). The research revealed greater social and geographical mobility and a marked 'loss of localism,' with many older white working-class people having a sense of having been 'abandoned by the flow of history' (Dench et al., 2006: 31).

Tim Cresswell (2006: 1) found that culture "no longer sits in places, but is hybrid, dynamic – more about routes than roots." Sociologists Anthony Elliot and John Urry provided an account of the global mobility of people and the impacts of mobility on the ways people lived and how they fashioned multiple identities and assumed 'portable personhood' (Elliot and Urry, 2010: ix). Elliot and Urry referred to the potential constraints on mobility in a post-modern and 'post-carbon' future.

The recent appeal of civil society has grown as a response to such processes of globalization and market change and the growth of state power and control. Civil society enables groups and individuals to organize themselves automatously – usually as free from state or corporate control as possible. According to Mary Kaldor (2003), civil-society groups can express group resistance to the impersonal globalizing forces of the market and state and potentially can build new communal identities. Kaldor et al. (2012) provide a comprehensive overview and compilation of the literature concerning civil society that demonstrates the interest of researchers across academic disciplines in the growth of civil activism in a globalizing world. Kaldor et al. (2012: 2) comment that not only in the West, "but also in growing parts of Asia and Latin America, Africa and the Middle East, today's generation are the children of the Internet, the mobile phone and cheap air travel – the 'globalization generation.' They know that the world is a singular fragile eco-system – and that while the national state does have a role to play, it is part of a broader global community."

Coda

The idea of the global community adds to the range of social conceptions of community, from the small-town community studies of the 1930s to the ghettoized communities of the 1960s, the postmodern fractile and mobile communities of globalization, and the global community itself. Sociologist Gerald Delanty (2003: 191–192) refers to the continued interest in community in the fields of sociology and other disciplines but notes that this reflects a 'radical pluralization' in which the 'forms of community are multiple' and the 'imaginary dimension of community' underlines 'the impossibility of community' as some universally agreed concept. Similarly, sociologist Zygmunt Bauman (2001: 3) has suggested that community "stands for the kind of world which is not, regrettably, available to us – but which we would dearly wish to inhabit and which we hope to repossess." This seems to confirm that community will continue as an enduring but ever-contested theme in sociology and in social and cultural theory.

Abstract

The term 'community' has been used by anthropology in a variety of ways and contexts. On a concrete ethnographic level, 'community' and 'community studies' have two main denotations. One is generic, echoing the interest anthropology and anthropologists have always had in ordinary, stable, small-scale localized collectives. The other pertains to studies of rural populations (e.g., villages, parishes, counties) and urban enclaves (e.g., neighborhoods and quarters) within industrialized, developed Western countries.

Analytically, the term tends to denote a syndrome rather than an accurately defined phenomenon. Used in various periods and within different theoretical orientations in reference to territorially based units, professional circles, solidarity groups and informal sociocultural amalgams, it could imply permanent collections with well-defined boundaries as well as loosely defined and transient formations.

The efficacy of the term 'community' as an interpretative tool was rather limited prior to the 1970s. New anthropological and ethnographic vistas since, however, have imbued it with more theoretical currency. It became, for example, a significant element in new anthropological tool-boxes developed for the analysis of rural groups in the northern, southern, and western margins of Europe. Later it found new uses as anthropologists began grappling with the need to conceptualize and historicize transnational social formations in a globalizing world.

The Concept of Community in the Social Sciences

Community, a rather ubiquitous and imprecise term in terms of social science theory, tends to be associated with an array of positive connotations, including solidarity, familiarity, common purpose, unity of values and a shared sense of identity. Earlier sociological debates of communities and their social significance stressed either a territorial base, i.e., groups whose members share a well-defined location (see Hawley, 1950), or, later, community as state of mind – a collective sharing of an underlying feeling of sameness and belonging regardless of geographical dispersion (see Bell and Newby, 1974). The latter option, while analytically promising and intellectually suggestive, produced a category which, while exceedingly popular, was also perplexing in its ambiguity. Since affiliation and identification with non-territorial communities can be unclear even to the actors themselves – let alone to social scientists attempting to characterize and study them – the concept can be (and has often been) used as an omnibus for a variety of related and unrelated meanings.

Not surprisingly, some sociological attention was given to the distinctions between the informal nature of communities and the more rigid structure of organizations (Gottshalk, 1975; Azarya, 1984) as well as to the problem of indeterminacy of community boundaries (Hillery, 1955). These not withstanding, community studies emerged since the 1920s and well into the 1980s as a solid branch of sociological inquiry, not least through the consistent preoccupation of the Chicago school with modernization and its impacts on urban culture, subcultures, and urban society.

Community (Re)Enters Anthropology

Anthropology, with its early emphasis on intensive field study focusing on small-scale groups whereby culture and society were assumed to be unproblematically linked to bounded space, had an inherent affinity with the view of communities as discernible sociocultural units. Habitually working with bounded communities, anthropologists tended to develop context-specific tools for their analysis. Early emphasis on customs and manners, the subsequent emergence of the concept of culture, the paradigms of structural functionalism, transactionalism, symbolic interaction, and structuralism *à la* Lévi-Strauss all offered, in their respective heydays, rich and convincing frameworks for studies of small-scale bounded groups. This may be the reason why the concept of community was not explored by anthropologists with any rigor, and why it was receiving limited critical attention in the discipline prior to the 1980s.

Thus, while the term community was always present in the anthropological lexicon, its syntactic status tended to be relegated to noun or synonym. It remained a finite idiom with limited interpretative power, its capacity to become a dynamic theoretical tenet largely arrested. Committed to depicting 'native' ways of explaining solidarity and social relations, and taken by the concept of an immutable culture occupying an ethnographic present, anthropologists had little use for the term *community*. And while Lynd and Lynd's classic study of Muncie (eternalized as *Middletown* in Lynd and Lynd, 1929), Lloyd Warner's *Yankee City* volumes (Warner and Lunt, 1941; Warner and Low, 1947) and Arensberg's work on the relationship between community and culture (see Arensberg and Kimball, 1965) undoubtedly inspired ethnographically oriented studies such as Robert Redfield's (1955) *The Little Community*, Marriott's edited volume on villages in India (Marriott, 1955) or Frankenberg's (1965) *Communities in Britain*, a strong and clear anthropological tradition of community studies was slow to materialize.

Two factors may have contributed to the emerging interest of anthropologists in the 1980s in the community as an analytical and theoretical category. One was the aforementioned

emergence in the 1960s and 1970s within sociology of the view of the community as a more abstract entity, whereby meaning and a sense of solidarity became more salient than tangible physical contact. The other was a growing need amongst anthropologists, by then more willing than ever before to study societies and cultures in the core and on the margins of Europe, to develop a theoretical toolbox for this new challenge.

An edited volume and an ethnography by Anthony Cohen (1982, 1985) indicated the efficacy of the concept of community for a more sophisticated understanding of the relationship between local rural and urban communities and wider affiliations and identity, not least the ones connected to the nation-state. The edited volume (Cohen, 1982) had six anthropologists writing two essays each about rural communities in Britain. One essay was incorporated into a section of the book entitled 'Belonging to the Part: Social Association within the Locality,' while the other was included in a section called 'Belonging to the Whole: The Community in Context.' The sections corresponded to the dual themes of the inquiry: how people develop a sense of belonging in a small community; and how they develop an identity and a set of practices that reflect their sense of place in the broader realm that lies beyond the local. The first theme naturally focuses on kinship, sect, regional histories, and affiliations. The second theme, pursued in Cohen's subsequent work, leads to a growing preoccupation with cultural boundaries and borders.

In terms of theory and analysis, the ethnographic attention paid by Cohen and his contributors to (mainly Celtic) rural Britain owes much to Clifford Geertz's emphasis on meaning and cultural interpretation. The community, according to Cohen's introduction to the volume, must be studied and interpreted not so much as a structured social organization but as an arena where experience is ordered, partly through a 'local' culture. This in turn produces a distinct local identity which is engaged in constant interplay with broader cultural formations, processes, and signals. Cohen's volume thus signposted a new field of inquiry, the form and theoretical approach of which were different from those of the adjoining anthropological arena of peasant studies, the latter focusing mainly on rural communities in semi-peripheral areas, including the margins of Europe and Latin America.

The importance attributed by Cohen to meaning and imagination, and the Wittgensteinian supremacy he advocates of context of use over lexical occurrence, become even clearer in *The Symbolic Construction of Community* (Cohen, 1985). Simple people too, he shows, are preoccupied with symbols, constantly using them to make comparisons (and sense) of appearance and reality, likeness and diversity, similarity and difference. Once more, social structure collapses at the feet of culture, subverting the monopoly of sociology over the concept of community. Significantly, more emphasis than ever before was now directed at the borders. Writers came to recognize that it is near boundaries and across them, that community culture and identity were being determined.

Community studies reduce methodological, analytical, and theoretical differences between anthropology and sociology. Conrad Arensberg's works of the 1950s and 1960s are by no means wholly sociological, and the same is true for Maurice Stein's *The Eclipse of Community* (Stein, 1960). By the same token, the strongly ethnographic turn of Warner's *Yankee City* volumes, West's *Plainville* (West, 1961) or the Lynds' *Middletown* (Lynd and Lynd, 1929) probably warrant counting them as anthropological, while the preoccupation displayed by Cohen (1982, 1985), Frankenberg (1965) and Hannerz (1980) with broad sociological issues merit labeling their works at least partly sociological.

Some writers have alluded to an obvious shortcoming of anthropological (and, for that matter, sociological) studies of communities – their propensity to be apolitical. Rich in analyses of inherent traits and characteristics, such studies lend themselves willingly to elaborate treatments of culture, cultural identity, and demarcation. This, however, can often serve as a cover for shying away from and even blindfolding themselves to issues of internal and external power disparities, political economy, and historicity (cf Aronoff, 1984; Cox, 1987).

A strength that anthropological studies of communities have had, at least since the 1980s, has been their emphasis on abstract experiences, not least imagination, as idioms shaping human identity and agency. Major inspiration for this project undoubtedly came from Benedict Anderson's work, not least from his creative employment of this notion in his seminal work on nationalism, *Imagined Communities* (Anderson, 1983). The focus on imagination resurfaced later in attempts to explore new ways in which anthropology could tackle the paradoxes and complexities of transnational experience and culture.

Critical Anthropology and the Concept of Community

Like 'ethnography,' 'the ethnographic present,' 'fieldwork,' 'informants,' and other key anthropological idioms, 'community' became, in the 1990s, a construct. Idealized as a composite, unproblematized pillar of old-guard anthropology, it could now serve as a hammering block against which critical ideas could be articulated.

Malkki (1997) looks at the connection between the concept of community and anthropology's propensity to look for the ordinary, durable, 'everyday' routines and practices. This approach, which gained for anthropology justified rewards and insights, gradually bred an expectation that all people studied by ethnographers are not just haphazard collections of humans somehow thrown together into the same location. Rather, they were expected to have always been part of a stable, permanent and – in particular – localized 'community.' But while such groups do of course exist, the emphasis on communities pushed anthropologists to overlook other possibilities, including those where life does create transient collections of humans randomly united. Such, Malkki (1997: p. 91) indicates, are what Barbara Myerhoff called *accidental communities* – Woodstock being a dramatic instance – and what Malkki herself found in refugee camps in Rwanda, where displaced people from a variety of places of origin huddled together, reinventing a sense of communal rootedness they may or may not have had in the lives they had before their dislocation.

Arjun Appadurai (1996), in his seminal work on the relationship between bounded place and culture in a world that is rapidly becoming dislocated, transnational, and diasporic, likewise uses an idealized icon of the term community in anthropology to develop a more sophisticated

concept of culture. Localities and communities, he asserts, must be historicized and contextualized, identified as processes of growth and shrinkage. Not least, anthropology should – and can – become more sensitive to what he calls the global production of locality.

Traditional concepts of community in the social sciences, as they had been applied to studies of rural Mexico, give Roger Rouse's (1991) study of migration into the USA a much needed structure against which to prop his concept of transnational migration. Earlier migration studies, he aptly indicates, had a bipolar picture, with culturally and demographically stable and homogeneous collectives on both ends. Immigrants, within this framework of analysis, simply moved – more or less successfully – between two 'communities.' His own ethnography, however, convinced him that what was taking place in fact was a more complex phenomenon, a translocal movement backward and forward. This productively subverts the wholesome view of the community – be it in rural Mexico or in the migrants' quarters of western USA – offering new tools for understanding of these complex and uneasy situations.

The new (twenty-first) century is yet to see a revival of the theoretical efficacy of the term 'community' in anthropology a renewal of its definitional powers as an ethnographic idiom. If anything, the vagueness of it, the silo capacity it has to denote an intuitive sense rather than index a specific phenomenon, is sometimes exploited for book or article titles (see for example Monterescu and Rabinowitz (2007)) which, while having an appeal for wider audiences, do not necessarily push the analytical prowess of the term to new terrains. Likewise, the choice of some departments in academic institutions, mainly in community college in the US, to change their names from 'Anthropology' to 'Community Studies' indicates a further resignation to the fact that rather than indicating theoretical precision, the term becomes suggestive of a fuzzier sense of solidarity and social cohesiveness which, for some, can represent what anthropology should stand for.

Community Supervision and Diversion in the United States

Lincoln B Sloas, Jennifer Lerch, and Faye S Taxman, Center for Advancing Correctional Excellence (ACE!), George Mason University, Fairfax, VA, USA

Abstract

With over 5 million adults on some form of community supervision, this article examines the current practices related to community supervision and diversion in the United States. Specifically, four types of diversion are outlined, including (1) complete diversion; (2) justice leverage diversion; (3) probation diversion; and (4) enhanced diversion. The empirical evidence surrounding each type of leverage is provided. A research agenda for the future is provided.

The vast majority of the offender population in the United States is not housed in correctional facilities but rather supervised in community settings (Petersilia, 2011; Maruschak and Parks, 2012). A report produced by the Pew Center on the States (2009) found that of the slightly more than 7 million individuals involved in the criminal justice system, approximately 70% were supervised in the community rather than being incarcerated. While the number of offenders under correctional control has declined slightly in recent years, the proportion of individuals supervised in the community has remained about the same (Maruschak and Parks, 2012; Carson and Sabol, 2012). In this article, the authors describe community supervision in the United States, focusing on one supervision model known as diversion.

What Is Community Supervision?

Community supervision in the United States encompasses the modes of correctional control where individuals are monitored in the community. The primary types of community supervision include probation or parole. Both serve as alternative punishments to incarceration by allowing the individual to serve their complete or partial sentence in the community. The primary distinction between probation and parole is that parole follows release from prison while probation can follow a short incarceration or be the criminal sanction alone (Maruschak and Parks, 2012). Prisons are correctional facilities where individuals are sent for incarceration sentences greater than 1 year, whereas jails are facilities where individuals are incarcerated for sentences lasting less than 1 year. For many jurisdictions within the United States, probation and parole supervision are interchangeable and community supervision agents monitor both types of cases.

While under community supervision, individuals are monitored by criminal justice agents who enforce the terms of conditions placed on them through either the court or a parole board. A large part of community supervision requires offenders to abide by conditions of their release. For example, this may include having a curfew, frequency of contacts with their parole/probation officer, and not carry firearms. Put simply, offenders' behavior is controlled as a way to get them to comply with conditions of their supervision.

The primary philosophy and goal of community supervision in the United States has ebbed and flowed between rehabilitation and punishment orientations over the last century. Sociopolitical context within the United States has often determined the strength of support for either of these paradigms (Garland, 2001; MacKenzie, 2001). The original foundation of community supervision as alternatives to imprisonment, while providing rehabilitation, originated in England in the mid-1800s. In the 1840s, John Augustus, known as the contemporary father of probation, requested that an alcoholic be released into his custody under supervision for duration of 3 weeks. After this time period, the alcoholic returned and informed the judge of his reform (Petersilia, 2011; Taxman, 2014). Parole followed in the footsteps of probation with the early work of Alexander Maconochie and Sir Walter Crofton (Morris, 2002). Maconochie believed offenders should be rewarded for good conduct and, eventually, earn early release. Referred to as the marks system, offenders could gain their freedom by accumulating enough marks for completing tasks asked of them. This focus on rehabilitation was largely reflected in community supervision practices before the 1970s. Beginning in the 1970s, there was a shift toward control and punishment as paradigms in the criminal justice system, which was reflected in community supervision with a focus toward surveillance rather than rehabilitation (MacKenzie, 2001).

Recently, the pendulum has begun to swing back toward rehabilitation; however, the vying between paradigms has created and altered various models of community supervision over time. Diversion programs in community supervision came about in the 1960s with various other supervision models focused around rehabilitation and case management (Lawrence, 1991). The aims of these programs were to provide appropriate services to individuals who came into contact with the criminal justice system and to reduce the stigmatizing impact the criminal justice system can have on individuals. The role of diversion programs has traditionally been to lessen the amount of contact individuals have with the criminal justice system, therefore reducing any negative social labeling arising from the contact (Lawrence, 1991). Additionally, diversion programs can act as a mechanism to reduce the severity of a punishment an offender will serve while under community supervision.

Community Supervision and Diversion

Originally, diversion programs fell into one of two types. The first type was complete or true diversion away from any formal processing by the criminal justice system. Through this model, individuals were least likely to be labeled or stigmatized through entering the criminal justice system and would instead receive necessary services to change their offending behavior (Lawrence, 1991). The second type was a leveraging stance where charges would be dropped if certain conditions were followed by the charged individual (Lawrence, 1991). This approach to diversion ensured the ability to enforce that required steps were taken by the offending individual to either receive treatment to change their behaviors or pay back the community or victim for wrong doing. This pay back could take forms such as community service or restitution.

As the philosophy of the criminal justice system moved away from a rehabilitation focus toward a punishment orientation, the types of diversion programs adapted with the changing goals. The original diversion types remained, but the punishment orientation of the criminal justice system helped develop two additional types of diversion models that focused more on control and punishment rather than on changing the individual's behaviors. One of these types can be called probation diversion. These are programs intended to be an alternative sanction to jailing individuals such as driving under the influence (DUI) programs. The second type is an enhanced probation diversion, which focuses on keeping higher risk individuals from entering prison.

All four types of diversion often involve legal pressures or coercion for individuals to participate in programming. Among the issues raised regarding legal coercion for treatment are ethical considerations of individual liberties and a lack of motivation among those coerced. Despite being of research interest for several decades, the use of legal pressure for treatment delivery, particularly for substance users, is still highly debated with mixed research findings (Klag et al., 2005). Some research finds that the severity of coercion or severity of the alternative punishment plays a part on the outcome (Hiller et al., 1998; Young et al., 2004). For instance, Young et al. (2004), assessing the Treatment Alternatives to Street Crime and Drug Treatment Alternative to Prison program as compared to other criminal justice referrals relying on less severe sentences, found individuals who were legally pressured into these two programs had lower levels of recidivism. We further discuss these four types of diversion programs in greater detail below.

Complete diversion, also referred to as true, prebooking, or precharge diversion, involves never allowing an individual to enter the court system to be processed by the criminal justice system. This type of diversion is typically initiated by police or medical/mental health professionals without the input of any community correction personnel. Complete or true diversion programs are typically reserved for juveniles, individuals with serious mental health disorders, substance use disorders, or co-occurring disorders who have committed a nonviolent, typically, misdemeanor offense. The goal of these programs is to increase access to needed treatment services that would prevent future, minor, criminal behavior from reoccurring.

Justice leverage diversion, also referred to as postbooking diversion, is when an individual is charged with an offense and goes to court, but offered to have the charges removed if they follow certain conditions. If the individual does not successfully complete the conditions, then they are processed through the criminal justice system with the charges remaining. Typically, the conditions to remove the charges are laid out by the court but overseen by the community supervision agency. In these instances, community supervision plays a vital role in determining whether an individual will have a criminal record or deemed successful at meeting the conditions for the charges to be lifted.

Probation diversion, or jail diversion, involves an individual who is adjudicated and sentenced by the court, but instead of being sentenced to jail time, the individual is ordered to be supervised in the community. Similar to the justice leverage diversion, conditions such as substance abuse treatment, mental health treatment, community service, or drug testing may be placed on the individual while in the community that they must follow or they will be sent to serve time in jail. However, in this type of diversion program, the charges remain even after the individual successfully completes the community supervision sentence. As with the other types of diversion, jail-based diversion programs are used with individuals with serious mental health diagnoses. The individual must be referred by a criminal justice actor (e.g., judge, lawyer) and then screened by a service provider (Lange et al., 2011; Lamberti and Weisman, 2004). After this process, individuals are either diverted into a treatment program or they can be completely diverted (Draine and Solomon, 1999).

Enhanced probation diversion, or prison diversion, includes community supervision programs that serve as an alternative either partially or completely to time in prison. These types of programs would typically be for individuals who are considered higher risk of reoffending and nonviolent who are in need of services that can be delivered in a community setting. Intensive supervision programs (ISPs) were intended to meet the need of this population by providing more tightly controlled community supervision than normal probation while reducing the number of individuals serving time in prison.

These four types of diversion programs, complete diversion, justice leverage diversion, probation diversion, and enhanced probation diversion, represent a framework for differentiating the various ways to manage offender populations in a community setting. Each of these types of diversion can be thought of as falling onto a continuum between the rehabilitation and punishment paradigms (Table 1). Complete

Table 1 Philosophical paradigms and diversion programs

Types of diversion	*Rehabilitation*	*Control*
Complete	+	−
Justice leverage	+	+
Probation diversion	−	+
Enhanced	−	+

+ = more emphasis; − = less emphasis.

diversion programs favor entirely a rehabilitative approach, whereas the probation and enhanced probation diversion have typically fallen completely into the paradigm of punishment. The justice leverage diversion program is typically seen as more of a balance between the paradigms. However, as we will discuss later, all of these diversion programs have the potential to find this balance between paradigms, which hopefully leads to improved individual outcomes and public safety. In the upcoming sections, we will discuss the prevalence of these types of diversion programs and the empirical evidence of each. The empirical evidence on the types of diversion programs is essential as to ascertain its relevance in the field of criminal justice.

Prevalence of Diversion Programs

Estimating the actual number of diversion programs used in the United States is presently beyond the scope of current research. Since most diversion programs are operated by local criminal justice agencies, determining a total number of programs overall for each of these four types would be an enormous undertaking. However, for some of the larger, more widely implemented programs, prevalence estimates are available.

Among complete diversion programs for adult populations, crisis intervention teams (CITs) are the most widely adopted across the country and world. As of 2008, there were an estimated 400 of these programs operating in the United States (Watson et al., 2008; Compton et al., 2008). Most recently, CIT International (2013) estimates that there are approximately 3000 of these programs operating internationally. A justice leverage diversion program that has been adopted across most of the country is that of problem-solving courts. As of 2009, there were 3648 total problem-solving courts operating in the United States (Huddleston and Marlowe, 2011). In 1992, Steadman et al. (1994) conducted a national survey of jails with a capacity of at least 50 inmates as identified through the American Jail Association. Of the 1263 jails surveyed, only 52 had a mental health jail diversion program that both screened for mental illness and used the program as either justice leverage or simply jail diversion.

These estimates provide a picture of the great variation in the number of these types of diversion programs operating in the United States. Recently, diversion programs, in the United States, have become more prevalent as a mechanism to divert offenders with mental health issues from the criminal justice system, including jail and prison (Lange et al., 2011). The growth of diversion programs comes in part from the support of organizations such as the Bureau of Justice Assistance and Substance Abuse and Mental Health Services Administration. Such agencies have recognized the need for diversion within criminal justice, particularly for the approximately 6–16% of offenders suffering from mental health-related issues (Ditton, 1999; Lamb and Weinberger, 1999). In the next section, we discuss the evidence as it pertains to complete diversion, justice-leverage diversion, probation diversion, and enhanced probation diversion programs.

What Do We Know About These Diversion Models?

Complete Diversion

Research on complete or true diversion programs with adult populations has largely been limited to programs focused on diverting individuals with serious mental illness or co-occurring disorders. The limited research does appear promising in that these diversion programs work to decrease criminal justice involvement and increase access to services within this specific population (Compton et al., 2008; Steadman and Naples, 2005; Steadman et al., 2000). However, the available research evidence is limited to CITs or other similar emergency/crisis response teams.

CITs are policing teams that receive specialized training to appropriately refer mentally ill individuals to mental health treatment services instead of involving them in the criminal justice system (Compton et al., 2008). This type of diversion program originated in Memphis, Tennessee, with the goals "to provide immediate response to and management of situations where the mentally ill are in a state of crisis; prevent, reduce, or eliminate injury to both the consumer and the responding police officer; find appropriate care for the consumer; and establish a treatment program that reduces recidivism" (Vickers, 2000: p. 2). There is some research indicating that CITs improve patient outcomes and increase the likelihood of receiving services sooner than those who enter the criminal justice system (Compton et al., 2008; Watson et al., 2010; Steadman et al., 2000). However, a recent study by Watson et al. (2010) found that the training did not impact arrest decisions made by officers. These authors also found the impact of training to be moderated by the officers' prior perceptions and knowledge of mental illnesses and services.

Despite the available research, there is still a lot unknown about complete diversion programs such as CIT. Most of the research is methodologically weak, examining only outcomes about officer perceptions rather than patient outcomes (Hartford et al., 2006; Compton et al., 2008). Lattimore et al. (2003) found that when comparing prebooking to postbooking diversion participants, prebooking participants were employed, had more education, less severe criminal history, mental health history, and substance use history, and overall more satisfied with life. More research needs to be done to understand the impact such differences among participants have on program effectiveness. Future research needs to explore how community supervision officers can impact these programs. For instance, these officers have a specialized knowledge regarding the availability of community resources for an underserved, criminal justice population that could potentially aid the effectiveness of these teams.

Justice Leverage Diversion

The most researched type of justice leverage diversion programs are problem-solving courts or specialty courts (Belenko, 2001). Specialty courts such as mental health courts and drug courts operate under the element of therapeutic jurisprudence. Rather than adhering to traditional forms of punishment, these courts seek to identify the etiology of offenders' behavior and treat it (Schneider, 2008). Since these courts are voluntary, offenders are provided with conditions to adhere to community

treatment that result in outcomes such as suspending their charges, sentencing, or probation (Griffin et al., 2002).

Much of the research on these courts is centered on the effectiveness of drug courts (Wilson et al., 2006; Rossman et al., 2011; Mitchell et al., 2012). In a meta-analysis of drug courts, Wilson et al. (2006) discovered, as a whole, drug courts reduced future offending for clients going through the program compared to those going through other correctional programs. In particular, they found that courts used as preplea or postplea models were most effective. Mitchell et al. (2012) supported this general finding, particularly among adult and driving while intoxicated (DWI) drug courts, and they also found that courts using either expungement or dismissal of charges greatly reduced drug recidivism. Recently, Rossman et al. (2011) conducted a multisite quasi-experimental design to examine the efficacy of drug courts as compared to control sites. Examining multiple outcome measures, the authors found that drug courts produced a significant impact in reducing both recidivism and substance use for clients. Additional benefits were detected for psychosocial outcomes, including employment and education as well as long-term impacts once the client had been out of drug court.

There is a growing body of research on other problem-solving courts such as mental health. Conducting a pre–post comparison of 386 misdemeanants in a mental health court, Henrinckx et al. (2005) found that these clients received more case management, management for their medication, and outpatient services after enrolling in the program. Mental health court clients also received fewer crisis services and inpatient treatment once enrolled in the program. In terms of recidivism, Henrinckx et al. (2005) discovered that more than half of the clients participating in the mental health court program experienced reductions in recidivism by more than half. Additionally, nearly two-thirds of clients experienced no new probation violations. In a similar study, Frailing (2010) used a quasi-experimental design on a sample of clients going through mental health court compared to sample of clients receiving treatment as usual. Frailing (2010) found for those clients participating in the mental health court significant reductions in both days incarcerated and substance used were experienced. In one randomized controlled trial (RCT) comparing mental health court clients receiving assertive community treatment, Cosden et al. (2005) found that clients participating in the mental health court with assertive community treatment had fewer new charges, reductions in substance abuse, fewer days in jail, and better improvements in mental health-related matters, including psychosocial functioning.

The evidence is very positive for the continued use of diversion programs in the form of problem-solving courts. The research shows through a variety of types of designs, including pre–post, quasi-experimental, and RCTs, problem-solving courts such as mental health courts and drug courts produce positive outcomes for clients who go through them. Despite these findings, though, more needs to be understood about problem-solving courts as well as other types of justice leverage diversion programs. The available research does not dissect the active ingredients within problem-solving courts (Wilson et al., 2006), thus making it not yet possible to conclude whether the nature of using them as a justice leverage diversion program drives the effectiveness.

Probation Diversion

Probation diversion programs include jail diversion (Shafer et al., 2004), postplea drug courts (i.e., after conviction) (Wilson et al., 2006; Mitchell et al., 2012), DUI diversion programs (Taxman and Piquero, 1998), and Proposition 36 (Farabee et al., 2004). Jail-based diversion programs have found some support in the empirical literature (Steadman et al., 1999). For instance, Lamberti et al. (2001) conducted a pre–post comparison of clients. The authors found that the average number of jail days as well as the average number of hospital days dropped and was statistically significant. Additionally, arrests, incarcerations, and hospitalizations were found to be reduced and statistically significant. However, other research has found no difference on outcomes between diverted individuals and nondiverted individuals with mental illness diagnoses beyond correctional cost savings (Steadman et al., 1999). Similarly, among postplea drug courts, meta-analysis finds them to be effective; however, recent results demonstrate that postplea drug courts are no more effective at reducing recidivism then preplea courts despite the threat of immediate severe sentencing available since conviction already occurred before the drug court experience (Wilson et al., 2006; Mitchell et al., 2012).

DUI diversion programs have been targeted at those individuals experiencing alcohol-related issues (Anson, 1987; Beck et al., 1999; Taxman and Piquero, 1998). For example, Anson (1987) examined the effectiveness of the Criminal Alcoholic Program using a longitudinal, pre–post design on a sample of client with criminal behavior, including alcohol-related issues. He found that the most statistically significant reductions in criminal behavior were for traffic offenses and alcohol offenses. Beck et al. (1999) tested the efficacy of an ignition interlock license reinstatement program on a sample of clients for 2 years. The study used an RCT and for those randomly assigned to the interlock group, significant reductions were experienced in terms of alcohol traffic violations in year one but no differences were detected in year two. These results led the authors to conclude the program ability to reduce alcohol-related offenses.

More recently, California has enacted Proposition 36 which is also known as the Substance Abuse and Crime Prevention Act (SACPA) (Farabee et al., 2004). This piece of legislation was voted on by Californians and seeks to act as a type of diversion for clients convicted of drug-related offenses. The purpose of the legislation is to use treatment as a diversion from incarceration. Comparing a sample of non-SACPA participants to SACPA participants, the researchers discovered that SACPA participants were more likely to experience being rearrested for a drug-related offense. The empirical research discussed in terms of jail-based and DUI diversion programs show some support in reducing future criminality of offenders but do not appear to be as strong as those discussed with justice leverage programs.

Enhanced Probation Diversion

Enhanced probation diversion programs come in the form of intermediate sanctions developed with the intent to reduce prison populations by supervising individuals more closely in

the community. The most prominent of this type of diversion are ISPs. These programs began in the 1980s as way to manage individuals deemed too dangerous for normal probation, but not serious enough for prison (Petersilia and Turner, 1993). ISPs vary greatly in what they include across the multitude of jurisdictions within the United States. Some of the common components are electronic monitoring (EM), drug testing, increased visits with community supervision agents, and home arrest (Petersilia and Turner, 1993). The findings regarding the effectiveness of ISPs has been mixed, with some research even finding that the closer supervision included in these programs actually increases recidivism (Turner et al., 1992; Petersilia, 1998).

Examining the use of intensive community supervision as a true prison diversion as compared to enhanced parole, Deschenes et al. (1995) looked at programs implemented in some Minnesota counties in the early 1990s. The programs included home detention, EM, required time on employment and education activities, drug testing, and frequent meetings with supervising agents. The authors found that, as a prison diversion, the intensive community supervision resulted in less time in prison, but more days on supervision than the control group. The prison diversion group had more technical violations than the control group, but there were no differences in new arrests. The intensive community supervision as an enhanced parole release did not have an impact.

ISPs have been criticized because while they were created to reduce prison intakes by serving as an intermediate sanction, some research has found that they ended up widening the net for less serious offenders who would have previously just been on probation (Petersilia and Turner, 1993; Byrne, 1990). In very few jurisdictions have ISPs actually been implemented as true prison diversion programs. Despite the overall negative findings, ISPs have been found to be effective when increased surveillance or punishment is used in tandem with treatment services to rehabilitate the offender (Petersilia, 1998). Similar support for this has been found in research conducted in Canada. Bonta et al. (2000) examined a program coupling EM and intensive evidence-based treatment. They found that EM alone had no impact, whereas the combined group was more likely to complete treatment at no greater risk to public.

In addition to ISPs, enhanced probation diversion includes some postplea drug courts. These drug courts provide similar levels of supervision as ISPs while addressing specific needs for substance users in the community.

Conclusions

Diversion programs are a widely used and supported form of community supervision, particularly for individuals with serious mental illness, substance use disorders, or co-occurring disorders. However, there is only limited research on the various types of diversion programs that are in operation. A key to furthering the research agenda across all four of these types is the investigation of legal pressure or coercion on individuals mandated to complete programming. All of these types of diversion exert coercive treatment upon individuals. Whether it is complete diversion where social workers and police directly order individuals to treatment or it is enhanced probation diversion where individuals must wear EM and go to drug court to stay out of prison, applied legal pressure is necessary for diversion to be successful.

The critiques offered by Klag et al. (2005) about the research conducted on the use of legal pressure with substance abusers offers a starting point for filling in the gap within the broader diversion program research base. These authors list five critiques of past coercion research as follows: (1) inadequate research designs, (2) poor measures for coercion, (3) no consistent definition of coercion, (4) unknown differences between voluntary and involuntary participants, and (5) lack of a continuum coercion measure. Research such as that conducted by Young et al. (2004) and Mitchell et al. (2012) begin to examine some of these inadequacies, but rigorous, clearly conceptualized research must examine differences between the amount/severity of coercion each of these program types uses. Understanding which, if any, of the legal pressures applied in these various diversion program types works best would provide an underlying basis for developing diversion programs aimed at best outcomes.

Furthermore, a common theme that runs throughout the available research is that diversion programs that strike a balance between the philosophical paradigms of rehabilitation and punishment tend to be the most effective. Such a form of community supervision has been termed behavioral management supervision (Taxman, 2014). Behavioral management supervision combines evidence-based practices (i.e., what research tells us works managing offenders) and treatment services. This type of supervision allows for community supervision agents to monitor and control individuals to protect public safety, but at the same time use evidence-based tools to promote individual change to prevent future criminal behavior. Advancing this balance between paradigms is important not only for community supervision practices overall, but also, as seen here, for specifically improving diversion programs.

Community Work

Kieron Hatton, School of Health Sciences and Social Work, University of Portsmouth, Portsmouth, UK

Abstract

Community work has been a dominant approach in delivering social welfare since the beginning of the twentieth century. This article considers the contested meaning of community, key theories in community work, and the close links between theory and practice. Focusing on three key thinkers, Alinsky, Gramsci, and Freire, developments in several countries' and NGOs' utilization of community development to further their agendas is examined. A short discussion of community youth development and social pedagogy is also provided with a conclusion of a reflection upon the potential efficacy of community work in achieving positive outcomes for marginalized communities across the globe.

Introduction

Notions of 'community,' a contested term, underpin community work. In this article, I examine definitions of 'community,' key theories in community work, and the links between theory and practice. I use three key thinkers, Alinsky, Gramsci, and Freire, to consider developments across Europe and how NGOs utilize community development to pursue their agendas. I end with a short discussion of community youth development and social pedagogy, and conclude by reflecting upon the potential usefulness of community work in achieving positive outcomes for marginalized communities everywhere.

Defining Community and Community Work

Community work as a paradigm within the work of human services or social professionals is a complex set of activities which can range from small, unfunded activities at a very local level (the street) to more complex activities at the level of communities, regions, or even across and between countries. At a political or philosophical level, it can encompass work which can be seen as unchallenging in that it meets needs which the state cannot or will not meet or as a radical and challenging approach which sees social justice as its primary focus and social change at the local, regional, national, or international levels as its overarching aim.

Part of the reason for this ubiquity is the concept of community itself. This is a highly contested concept which is appropriated by the right and left to support claims of accountability and relevance. As a major social theorist says:

> Community can be the warmly persuasive word used to describe an existing set of relationships. What is most important, perhaps, is that unlike all other terms of social organisation (state, society, nation) it seems never to be used unfavourably and given any opposing term.
>
> Williams, 1976: p. 77

'Community' is one of the most widely used and misused words in social science. It is often used indiscriminately to enhance the appeal of policies, which may themselves be unattractive – community policing, community safety, community partnership, community school, e.g., when the old Borstals were renamed in this manner in the UK. Day (2006) notes that it is often used in an ill-defined and vague way as "an excuse for not thinking hard enough about what exactly it is that people have in common … alluring in its promise but to be approached with extreme care" (Day, 2006: p. 2). What then does it mean?

Tonnies (1955) used the idea of community to describe the transformation in social relationships brought on by modernization (Breuggemann, 2006). Bauman (2001) sees community as a counterbalance to the atomization and individualization of a globalizing world and as a way through which control can be gained or regained. He argues that

> We all need to gain control over the conditions under which we struggle with the challenges of life – but for most of us such control can be gained only collectively.
>
> Bauman, 2001: p. 149

Delanty and Styrom (2003) sees community as a new way of understanding kinds of belonging with multiple and overlapping relationships at its center. The boundaries of community are contested and community in this sense is more a discourse with a focus on, "an imagined condition than a symbolically shaped reality based on fixed reference points" (p. 188). For the purpose of this article, I conceptualize community as an alternative to individualistic discourses which atomize people's experience and suggest instead ways in which people can regain control over their lives and build positive relationships which promote well-being. These dichotomies in the theorization of community reflect divergences in discourses around community work which I examine later.

Community Work – Key Theories and Theorists

Mayo (2008) argues that there were three stages in the development of community work. The first, she characterizes as the postcolonial legacy (during the 1960s) – the period when British community development reinvented itself; a period of optimism. The original colonial focus on winning the 'hearts and minds' of local indigenous peoples was replaced with a restructuring of Western economies, a fear of the consequences of the Cold War, and the growth of community

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28018-5

activism. The second stage revolved around community work's relationship with the state. Community work was originally seen by western/northern states as a means of resolving social problems, which were primarily caused by the inadequacies of poor and marginalized communities who were unable to manage their own affairs and needed 'experts' to assist them to do so (the 'social pathology' model of social change). Radical community workers soon recognized that the problems facing many of the areas in which they worked had similar causative factors (high unemployment and high levels of poverty, the restructuring of industry, the movement of finance capital outside of these areas). The social pathology paradigm was therefore replaced with a structural/Marxist analysis of the state and the role of community work within it.

A number of attempts have been made to conceptualize community work. The UK's *Gulbenkian Report* published in 1973 drew a distinction between community development and community action. The former is defined as based on consensus, is client-centred and an approach that has the community worker in an enabling role. It was based more on community consultation than community control. In community action, the Report's authors argued, the capacity to "appoint, dismiss and define the role of workers lies within the group itself" (p. 49). They conclude that, in contrast, "an outstanding characteristic of community action is the involvement of the socially deprived – the very ones usually excluded from other organizations – in order to improve their situation" (p. 50).

Stepney and Popple (2008) note a similar distinction. They characterize the community development approach as a reformist approach in which power is dispersed and exercised by the mass of people rather than a small elite or class. They note, "It encourages participation and prevents power being concentrated in the hands of the few" (Stepney and Popple, 2008: p. 139). This community action approach, they now characterize as transformative community action. Advocates of this approach argue that power is, 'concentrated in relatively few hands' and suggest: that, community work, "is more likely to adopt a radical approach that advocates far reaching and wide spread changes … it promotes autonomous ways of working through collective action to address moral and political issues."

Stepney and Popple, 2008: p. 140

It has been suggested that community work can be part of an oppositional politics which provides an alternative to neo-liberalism (De Filippis et al., 2009). De Filippis et al. suggest that "community organizations need to look beyond the local and incorporate a political and social analysis of the wider political economy into their work" (p. 50). Popple (1995) argues that community work has the potential to feed into debates surrounding social movements. The benefit for community work is an expanded understanding of macroforces which shape and impinge upon individuals and communities (p. 53). He draws a distinction between pluralist, radical/socialist, feminist, and antiracist community work. Briefly, these can be characterized as follows.

Pluralist Community Work

Pluralist community work, Popple argues, features a dispersal of power in which different stakeholders reach compromises rather than imposing their own solutions on communities. In a pluralist framework, power is equally shared and different stakeholders will be more influential at different times. The state's role becomes one of balancing competing interests and ensuring fairness. For the community worker, this means encouraging participation and the achievement of small-scale localized reforms. This approach lays considerable importance on the development of skills. Good practice becomes defined in relation to technical competence rather than values.

Radical and Socialist Community Work

Radical and socialist community work dates primarily from the 1960s and 1970s. It has involved community workers in advocating for large-scale change in the political, social, and economic system. Radical community work is often associated with anarchism and the belief that the state in particular is problematic and all existing structures need to be dismantled if real improvements are to be achieved. In some cases, echoes of this approach can be found in syndicalist and situationalist writings and activities at the beginning of the twentieth century.

However, it also incorporates the socialist tradition(s) from two primary sources: Fabianism and Marxism. Fabianism has its roots in the writings of GDH Cole and emphasizes the potential for achieving change within existing state structures. Unlike pluralism, with which it is sometimes associated, it does not confine itself to microlevel change and argues that the state can be appropriated for the benefit of people currently excluded from power. Fabianism does not, however, challenge the legitimacy of the state suggesting that social change should be gradual and not conflictual.

Marxist analysts see the state as reinforcing class inequality and argue that capitalist social relations and structures need to be overturned if lasting change is to be achieved (Purcell, 2012). This can be achieved by being 'in and against the state' and could happen when state workers, through their trade unions or other representative organizations work with local community activists to bring together a larger movement for change.

The London-Edinburgh Weekend Return Group (1980) and Bolger et al. (1981) argued that there was a need to take account of the potential of state employees to work within the state in a progressive way that could transform welfare capitalism into welfare socialism. They recognized the value of trying to find the oppositional space successfully to undertake work that sustains a struggle against the state (Popple, 1995: p. 36).

Feminist Community Work Theories

Feminist community work posed a challenge to the male-dominated community work theory in the late 1970s, arguing that there were specific factors in common between the growth of the second-wave feminism and the rise of community action by drawing links between personal and political action (Dominelli, 1990, 2006). Some feminist writers and activists, e.g., Morgan (1970), were criticized by black feminists like Lorde (1984) and Hill-Collins (1990) for concentrating primarily on the experience of white, middle-class women and playing down the marginalized experiences of black women.

Ledwith suggests that "white feminists stood accused of defining women from a White perspective, exposing a White power which has the arrogance to overlook other aspects of difference" (2009: p. 691) and argues for the incorporation of Gramsci into feminist debates. She says that Gramsci provided "the conceptual tools to make sense of my own life experience" (p. 695) and enables antioppressive activists to analyze and address, "the complex interconnectedness of a loci of oppressions" (p. 696).

Black and Antiracist Theories

Black and antiracist theories emphasize the link between race, class, and gender. They draw on black radicalism, socialism, Marxism, and black feminism. Central to this approach is the argument that state policy acted as a repressive force on black people (Ohri et al., 1982). Black and antiracist community workers developed a critique of society by focusing on how oppression/discrimination operate at personal, institutional, and structural levels. Importantly for community work it highlighted the need for white and black community workers to challenge racism in all its manifestations and the significant space that community work provides for communities and groups to develop their own cultural formations and organizations.

Dominelli (1998: p. 54) has suggested that:

> people from subordinated ethnic groups have had to develop their own services and to ensure that these services are capable of meeting their needs and can be used to challenge inadequate mainstream provisions.

Ife and Fiske (2006) argue that community development can contribute to tackling racism by promoting a human rights perspective predicated on a bottom–up approach to tackling structural oppression. In particular they point to how, "community based education, consciousness raising campaigns and ongoing movements at every level of society" (p. 300) can have a significant impact on public sentiments and contribute to developing an antiracist theory and practice.

Key Thinkers and Activists: Praxis

Central to understanding community work is the way that theoretical discourses are not standalone activities but provide understandings to guide action that leads to social change. Three theorists/activists who have had a significant impact on the development of community work, and who come from different traditions, are Saul Alinsky, Antonio Gramsci, and Paulo Freire. Each demonstrates in his own way as to how the synthesis of theory and action – *praxis* – can contribute to successful strategies of social change.

Alinsky

Alinsky was a radical community organizer in Chicago. He believed that if social and community change was to occur, an activity had to be underpinned with recognition of how power operates. In *Reveille for Radicals* (1969) he said:

> The organizer must be able to communicate and convince the people, that if they find a way to join together, they need not fatalistically accept their plights but will have the power to affect the shape of the world (p. 209).

> However his emphasis was on pragmatism and the development of achievable goals. He believed in the centrality of tactics and the need to constantly outthink the '*enemy*.' He argued that it was important to maintain constant pressure on the opposition. To achieve this he developed what he called 'power tactics' which he outlined in *Rules for Radicals* (1972). He suggested that "tactics is the art of how to take and how to give … our concern was with the tactic of taking" (p. 126).

Among the rules of power tactics he outlined were concerns with:

- acting outside of the opponents' experience and reacting quickly to the actions, and counteractions, of opponents;
- making sure that those involved in the campaign enjoyed it; and
- keeping the pressure on.

> Bunyan (2010) notes the centrality of power to Alinsky's work, in particular, "the importance of local institutions in the everyday lives of people … and the potential for such institutions to become the basis of a power organization that could act on the issues and concerns that mattered most to them" (p. 114). Alinsky argued the importance of education as a key element in the promotion of change and suggested that, education enabled people to make sense of the world in which they lived and consequently to "make informed and intelligent judgements."
>
> 1972: p. 124 about it

Alinsky's approach was influential within community work internationally, including the UK, Canada, Australia, and Hong Kong. While some people welcomed an approach that focused on organizing effectively and confronting real-world power relationships, others felt that his analysis lacked a broader framework for understanding how power operates. His writings and his campaigns highlighted tensions within the US and predicated on a pluralist analysis of society. He believed that people could achieve power within the locality or city, a belief that assumed that power was accessible if you had the tools to access it. As such, he ignored, or at least downplayed, structural inequalities such as class, race, and gender (Dominelli, 2006). Alinsky's ideas were supplemented by other writers who saw the potential for change from within a more sophisticated theoretical framework. Gramsci and Freire provide this theoretical framework.

Antonio Gramsci

Gramsci, an Italian Marxist active in establishing workers councils in Turin in the 1920s, rejected a simplistic version of Marxism which focused only on class relations. He developed a broader conception of politics which focused on the struggle for moral and political leadership through a process that he called *hegemony*. He argued that ruling classes dominate

through a mixture of force and consent where the consent is gained through their assuming the political, moral, and intellectual leadership in society. Gramsci saw civil society organizations as places where democratic struggles could be linked together to maintain hegemony.

The ruling class, he argued, retains control by making their rule and its legitimacy appear like 'common sense.' It is then the role of external agents such as intellectuals, union organizers, and community leaders to challenge common sense notions. Gramsci held that an oppressed group needs its own *organic intellectuals* (those that emerge from within their own ranks) to challenge these dominant ideas. He believed that social change could occur through the construction of alliances between industrial workers and civil society organizations but that organic intellectuals would have a key role in such alliances. Gramsci, talking about peoples' capacity to reflect upon their world says:

> 'everyone' is a philosopher … it is not a question of introducing from scratch a scientific form of thought into everyone's individual life, but of renovating and making 'critical' an already existing activity.
> Gramsci, 1971: pp. 330–331, cited in Allman, 2001: p. 114
